As early as the first few months of life, infants smile and return friendly behaviors to their reflection in a mirror. When do they realize that the baby smiling back at them is the self?

Beginnings of Self-Awareness At birth, infants sense that they are physically distinct from their surroundings. For example, newborns display a stronger rooting reflex in response to external stimulation (an adult's finger touching their cheek) than to self-stimulation (their own hand contacting their cheek) (Rochat & Hespos, 1997). Newborns' remarkable capacity for *intermodal perception* (see page 166 in Chapter 4) supports the beginnings of self-awareness (Rochat, 2003). As they feel their own touch, feel and watch their limbs move, and feel and hear themselves cry, babies experience intermodal matches that differentiate their own body from surrounding bodies and objects.

Over the first few months, infants distinguish their own visual image from other stimuli, but their self-awareness is limited—expressed only in perception and action. When shown two side-by-side video images of their kicking legs, one from their own perspective (camera behind the baby) and one from an observer's perspective (camera in front of the baby), 3-month-olds looked longer at the observer's view (see Figure 11.1a). In another video-image comparison, they looked longer at a reversal of their leg positions than at a normal view (see Figure 11.1b) (Rochat, 1998). By 4 months, infants look and smile more at video images of others than at video images of themselves, indicating that they view another person (as opposed to the self) as a potential social partner (Rochat & Striano, 2002).

This discrimination of one's own limb and facial movements from those of others in real-time video presentations reflects an *implicit sense of self–world differentiation.* It serves as the foundation for *explicit self-awareness:* an objective understanding that the self is a unique object in a world of objects, which includes representations of one's own physical features and body dimensions.

Explicit Self-Awareness During the second year, toddlers become consciously aware of the self's physical features. In several studies, 9- to 28-month-olds were placed in front of a mirror. Then, under the pretext of wiping the baby's face, each mother rubbed red dye on her child's nose or forehead. Younger babies touched the mirror as if the red mark had nothing to do with them. But those older than 20 months rubbed their noses or foreheads, indicating awareness of their unique facial appearance (Bard et al., 2006; Lewis & Brooks-Gunn, 1979). And some toddlers act silly or coy in front of the mirror, playfully experimenting with the way the self looks (Bullock & Lutkenhaus, 1990).

Around age 2, **self-recognition**—identification of the self as a physically unique being—is well under way. Children point to themselves in photos and refer to themselves by name. In fact, mirror self-recognition predicts other milestones that reflect representation of the self, including use of personal pronouns ("me," "my," "mine") and emergence of make-believe play (Lewis & Ramsay, 2004). Soon children identify themselves in images with less detail and fidelity than mirrors. Around age 2½, most reach for a sticker surreptitiously placed on top of their heads when shown themselves in a live video, and around age 3, most recognize their own shadow (Cameron & Gallup, 1988; Suddendorf, Simcock, & Nielsen, 2007).

© LAURA DWIGHT PHOTOGRAPHY

This 20-month-old's response indicates that she recognizes her unique physical features and is aware of herself as a separate being, distinct from other people and objects.

As self-recognition takes shape, older toddlers also construct an explicit body self-awareness. They realize that their own body can serve as an obstacle. When asked to push a shopping cart while standing on a mat attached to its rear axle, most 18- to 21-month-olds (but not younger children) figured out how to remove themselves from the mat so the cart would move—an ability that improved with age (Moore et al., 2007).

Nevertheless, toddlers lack an objective understanding of their own body dimensions. They make **scale errors,** attempting to do things that their body size makes impossible. For example, they will try to put on dolls' clothes, fit themselves into a doll-sized chair, or walk through a doorway too narrow for them to pass through (Brownell, Zerwas, & Ramani, 2007; DeLoache, Uttal, & Rosengren, 2004). Scale errors decline around age 2, but many 2½-year-olds still make them. Young preschoolers are still learning to process physical information about their own bodies in they same way they do for other objects.

LOOK and LISTEN

Ask several parents of 1½- to 2-year-olds if they have observed any instances of scale errors. Have the parent hand the toddler doll-sized clothing (hat, jacket, or shoe) or furniture (table, chair, or slide) and watch for scale errors.

Influences on Self-Awareness What experiences contribute to gains in self-awareness? During the first year, as infants act on the environment, they probably notice effects that help them sort out self, other people, and objects (Nadel, Prepin, & Okanda, 2005; Rochat, 2001). For example, batting a mobile and seeing it swing in a pattern different from the infant's own actions informs the baby about the relation between self and physical world. Smiling and vocalizing at a caregiver who smiles and vocalizes back help clarify the relation between self and social world. And watching the movements of one's own hands and feet provides still another kind of feedback—one under much more direct control than the movements of other people or objects. The contrast between these experiences helps infants sense that they are separate from external reality.

Researchers do not yet know exactly how toddlers acquire the various aspects of explicit self-awareness. But sensitive caregiving seems to play a role. Compared to their insecurely attached agemates, securely attached toddlers display more complex self-related actions during play, such as making a doll labeled as the self take a drink or kiss a teddy bear. They also show greater knowledge of their own and their parents' physical features—for example, in labeling of body parts (Pipp, Easterbrooks, & Brown, 1993; Pipp, Easterbrooks, & Harmon,

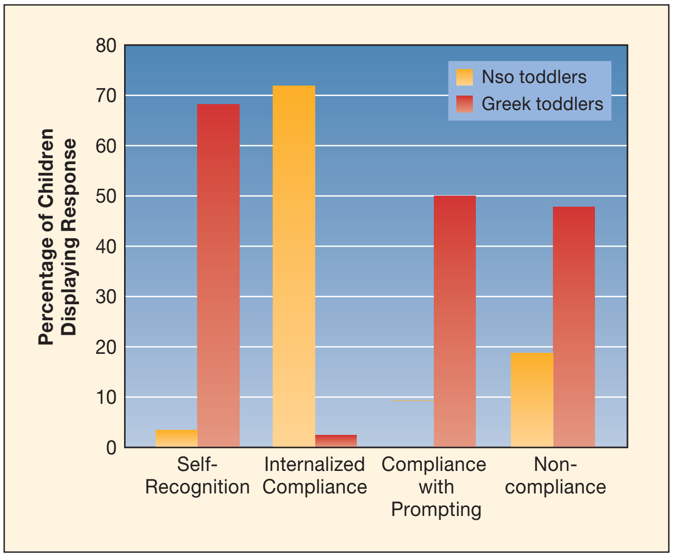

FIGURE 11.2 **Self-recognition and compliance among Nso and Greek toddlers.** At 18 to 20 months, toddlers were tested for mirror self-recognition and for compliance (they were told not to open a transparent container with an attractive food). Among Greek toddlers, whose culture values independence, many more had attained self-recognition. But Nso toddlers, reared in an interdependent culture, were greatly advanced in compliance (following directions without prompting), whereas Greek toddlers either needed reminders or did not comply. (Adapted from Keller et al., 2004.)

1992). And 18-month-olds who often establish joint attention with their caregivers are advanced in mirror self-recognition (Nichols, Fox, & Mundy, 2005). Joint attention offers toddlers many opportunities to compare their own and others' reactions to objects and events, which may enhance toddlers' awareness of their own physical uniqueness.

Cultural variations exist in early self-development. Urban German and Greek toddlers attain mirror self-recognition earlier than toddlers of the Nso people of Cameroon, a collectivist rural farming society that highly values social harmony and responsibility to others (Keller et al., 2004, 2005). Compared to their German and Greek counterparts, Nso mothers engage in less face-to-face communication and object stimulation and more body contact and physical stimulation of their babies. German and Greek practices reflect a *distal parenting style* common in cultures that value *independence;* the Nso practices a *proximal parenting style* typical in cultures that value *interdependence.* In line with these differences, Nso proximal parenting is associated with later attainment of self-recognition but earlier emergence of toddlers' compliance with adult requests (see Figure 11.2).

Self-Awareness and Early Emotional and Social Development

Self-awareness quickly becomes a central part of children's emotional and social lives. In the final months of the first year, as infants start to behave intentionally, they learn that their own goals (touching a breakable object, grabbing a peer's toy) frequently conflict with the goals of others. Soon, they realize that the self can be the focus of others' intentions and emotional reactions. As a result, they become increasingly sensitive to variations in caregivers' emotional messages (Thompson, 2006). This sets the stage for social referencing and, in the middle of the second year, emergence of self-conscious emotions (see pages 414 and 408 in Chapter 10).

Self-awareness also leads to first efforts to understand another's perspective. We have seen in previous chapters that toddlers increasingly appreciate others' intentions, feelings, and desires. They also begin to empathize (see page 415). Furthermore, mirror self-awareness precedes sustained, mutual peer imitation—a partner banging an object, the toddler copying the behavior, the partner imitating back, and the toddler copying again (Asendorpf, Warkentin, & Baudonniere, 1996). These exchanges indicate that the toddler not only is interested in the playmate but also realizes that the playmate is interested in him or her.

Two-year-olds' self-recognition leads to a sense of ownership. The stronger their self-definitions, the more possessive 2-year-olds tend to be, claiming objects as "Mine!" (Fasig, 2000; Levine, 1983). A firmer sense of self also enables children to cooperate in resolving disputes over objects, playing games, and solving simple problems (Brownell & Carriger, 1990; Caplan et al., 1991). Accordingly, when trying to promote friendly peer interaction, parents and teachers can accept young children's possessiveness as a sign of self-assertion ("Yes, that's your toy") and then encourage compromise ("but in a little while, would you give someone else a turn?"), rather than insisting on sharing.

The Categorical, Remembered, and Enduring Selves

By the end of the second year, language becomes a powerful tool in self-development. Because it permits children to represent and express the self more clearly, it greatly enhances self-awareness. Between 18 and 30 months, children construct a **categorical self** as they classify themselves and others on the basis of perceptually distinct attributes and behaviors—age ("baby," "boy," or "man"), gender ("boy" or "girl"), and physical characteristics ("big," "strong"). They also start to refer to the self's goodness and badness ("I good girl." "Tommy mean!") and competencies ("Did it!" "I can't") (Stipek, Gralinski, & Kopp, 1990).

Recall from Chapter 7 that adult–child conversations about the past lead to an autobiographical memory. This life-story narrative grants the child a **remembered self**—a more

CULTURAL INFLUENCES

Cultural Variations in Personal Storytelling: Implications for Early Self-Concept

Preschoolers of many cultural backgrounds participate in personal storytelling with their parents. Striking cultural differences exist in parents' selection and interpretation of events in these early narratives, affecting the way children view themselves.

In one study, researchers spent hundreds of hours over a two-year period studying the storytelling practices of six middle-SES Irish-American families in Chicago and six middle-SES Chinese families in Taiwan. From extensive videotapes of adults' conversations with 2½-year-olds, the investigators identified personal stories and coded them for content, quality of their endings, and evaluation of the child (Miller, Fung, & Mintz, 1996; Miller et al., 1997).

Parents in both cultures discussed pleasurable holidays and family excursions in similar ways and with similar frequency. But Chinese parents more often told long stories about the child's misdeeds—using impolite language, writing on the wall, or playing in an overly rowdy way. These narratives were conveyed with warmth and caring, stressed the impact of misbehavior on others ("You made Mama lose face"), and often ended with direct teaching of proper behavior ("Saying dirty words is not good"). By contrast, in the few instances in which Irish-American stories referred to transgressions, parents downplayed their seriousness, attributing them to the child's spunk and assertiveness.

Early narratives about the child seem to launch preschoolers' self-concepts on culturally distinct paths (Miller, Fung, & Koven, 2007). Influenced by Confucian traditions of strict discipline and social obligations, Chinese parents integrated these values into their stories, affirming the importance of not disgracing the family and explicitly conveying expectations in the story's conclusion. Although Irish-American parents disciplined their children, they rarely dwelt on misdeeds in storytelling. Rather, they cast the child's shortcomings in a positive light, perhaps to promote self-esteem.

Whereas most Americans believe that favorable self-esteem is crucial for healthy development, Chinese adults generally see it as unimportant or even negative—as impeding the child's willingness to listen and to be corrected (Miller et al., 2002). Consistent with this view, the Chinese parents did little to cultivate their child's individuality. Instead, they used storytelling to guide the child toward socially responsible behavior. Hence, the Chinese child's self-image emphasizes membership in the collective and obligations to others, whereas the North American child's is more autonomous (Wang, 2006b).

ECOPIX-ULLSTEIN BILD/THE GRANGER COLLECTION

A Chinese mother speaks gently to her children about proper behavior. By pointing out how children's misdeeds affect others, Chinese parents promote a self-concept that emphasizes social obligations.

coherent portrait than is offered by the isolated, episodic memories of the first few years. By participating in personal storytelling, children come to view the self as a unique, continuously existing individual embedded in a world of others. As early as age 2, parents use these discussions to impart rules, standards, and evaluative information about the child, as when they say, "You added the milk when we made mashed potatoes. That's a very important job!" (Nelson, 2003). As the Cultural Influences box above reveals, these narratives are a major means through which caregivers imbue the young child's sense of self with cultural values.

As they talk about personally significant events and as their cognitive skills advance, preschoolers gradually develop an **enduring self**—a view of themselves as persisting over time. Not until age 4 are children certain that a video image of themselves replayed a few minutes after it was filmed is still "me" (Povinelli, 2001). Similarly, when researchers asked 3- to 5-year-olds to imagine a future event (walking next to a waterfall) and to envision a future personal state by choosing from three items (a raincoat, money, a blanket) the one they would need to bring with them, performance—along with future-state justifications ("I'm gonna get wet")—increased sharply between ages 3 and 4 (Atance & Meltzoff, 2005).

The Inner Self: Children's Theory of Mind

As children think more about themselves and others, they form a naïve *theory of mind*—a coherent understanding of their own and others' rich mental lives. Recall from our discussion of metacognition in Chapter 7 that after age 2, preschoolers refer to mental states frequently and appropriately in everyday language. Although they confuse certain mental terms (see page 303), they are clearly aware of an **inner self** of private thoughts and imaginings.

How does the young child view this inner self, and how does this view change with age? Investigators are interested in this question because ideas about the mind are powerful tools in explaining and predicting both our own and others' everyday behaviors. Children's developing theory of mind contributes vitally to **perspective taking**—the capacity to imagine what others may be thinking and feeling and to distinguish those viewpoints from one's own. Perspective taking, in turn, is crucial for a wide variety of social–cognitive achievements, including understanding others' emotions (Chapter 10), referential communication skills (Chapter 9), and (as we will see shortly) self-concept and self-esteem.

Early Understandings of Mental States

Over the first year of life, infants build an implicit appreciation of people as animate beings whose behavior is governed by intentions, desires, and feelings. This sets the stage for the verbalized mental understandings that blossom in early childhood.

In Chapter 10, we saw that 3-month-olds smile more at people than at objects and become upset when a person poses a still face and fails to communicate. By 6 months, when infants see people talk, they expect the talk to be directed at other people, not at inanimate objects (Legerstee, Barna, & DiAdamo, 2000). At the end of the first year, babies view people as intentional beings who can share and influence one another's mental states, a milestone that opens the door to new forms of communication—joint attention, social referencing, preverbal gestures, and language. These early milestones serve as the foundation for later mental understandings. In longitudinal research, 10-month-olds' ability to discern others' intentions predicted theory-of-mind competence at age 4 (Wellman et al., 2008).

At the end of the second and continuing over the third year, children display a clearer grasp of people's emotions and desires, evident in their increasing mental-state vocabulary, capacity to empathize, and realization that people often differ from one another and from themselves in likes, dislikes, wants, needs, and wishes ("Mommy likes green beans. Daddy doesn't. He likes carrots. I like carrots, too!") (Cassidy et al., 2005; Rakoczy, Warneken, & Tomasello, 2007). Still, appreciating the distinction between others' desires and one's own develops gradually. Whereas 18-month-olds can take into account differences in food preferences using another's emotional expression (see page 415 in Chapter 10), 2- and 3-year-olds continue to have difficulty with more challenging tasks—such as selecting a gift for someone based on that person's desires (Atance, Bélanger, & Meltzoff, 2010). As children gain experience in observing what others like and dislike, their performance improves.

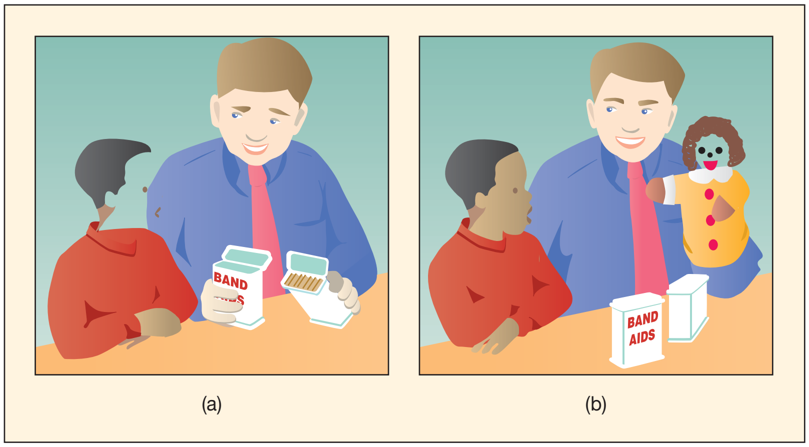
These findings confirm that toddlers and young preschoolers comprehend mental states that can be readily inferred from their own and others' actions. But their understanding is limited to a simplistic **desire theory of mind:** They think that people always act in ways consistent with their desires and do not realize that less obvious, more interpretive mental states, such as beliefs, also affect behavior (Bartsch & Wellman, 1995).

Development of Belief–Desire Reasoning

Between ages 3 and 4, children increasingly refer to their own and others' thoughts and beliefs (Wellman, 2011). And from age 4 on, they exhibit a **belief–desire theory of mind,** a more advanced view in which both beliefs and desires determine actions, and they understand the relationship between these inner states (Gopnik & Wellman, 1994; Ziv & Frye, 2003). Turn back to the beginning of this chapter, and notice how 4-year-old Ellen deliberately tries to alter her mother's *belief* about the motive behind her pretending, in hopes of warding off any *desire* on her mother's part to punish her. From early to middle childhood, efforts to alter others' beliefs increase, suggesting that children more firmly realize the power of belief to influence action.

Dramatic evidence for preschoolers' belief–desire reasoning comes from games that test whether they realize that *false beliefs*—ones that do not represent reality accurately—can guide people's behavior. **TAKE A MOMENT...** Show a child two small closed boxes, one a familiar Band-Aid box and the other a plain, unmarked box (see Figure 11.3). Then say, "Pick the box you think has the Band-Aids in it." Children usually pick the marked container. Next, open the boxes and show the child that, contrary to her own belief, the marked one is empty and the unmarked one contains the Band-Aids. Finally, introduce the child to a hand puppet and explain, "Here's Pam. She has a cut, see? Where do you think she'll look for Band-Aids? Why would she look in there? Before you looked inside, did you think that the plain box contained Band-Aids? Why?" (Bartsch & Wellman, 1995; Gopnik & Wellman, 1994). Only a handful of 3-year-olds can explain Pam's—and their own—false beliefs, but many 4-year-olds can.

Some researchers claim that the procedures just described, which require verbal explanations, grossly underestimate younger children's ability to attribute false beliefs to others. Relying on the violation-of-expectation method (which depends on looking behavior), these investigators assert that children comprehend others' false beliefs by age 15 months (Baillargeon, Scott, & He, 2010). But like other violation-of-expectation evidence, this conclusion is controversial (see Chapter 6) (Ruffman & Perner, 2005; Sirios & Jackson, 2007). In another study relying on active behavior (helping), most 18-month-olds—after witnessing an object moved from one box to another while an adult was not looking—helped the adult, when he tried to open the original box, locate the object in the new box (Buttelmann, Carpenter, & Tomasello, 2009). Still, much more evidence is needed to confirm that toddlers implicitly grasp mental states as complex as false belief (Poulin-Dubois, Brooker, & Chow, 2009). Indeed, their performance may be based on a far simpler rule: *lack of perceptual access leads to not knowing*—that a person who hasn't seen the contents of a particular container can't know what's in it and, therefore, will be mistaken (Fabricius & Khalil, 2003).



(a) (b)

FIGURE 11.3 Example of a false-belief task. (a) An adult shows a child the contents of a Band-Aid box and an unmarked box. The Band-Aids are in the unmarked container. (b) The adult introduces the child to a hand puppet named Pam and asks the child to predict where Pam would look for the Band-Aids and to explain Pam's behavior. The task reveals whether children understand that without having seen that the Band-Aids are in the unmarked container, Pam will hold a false belief.

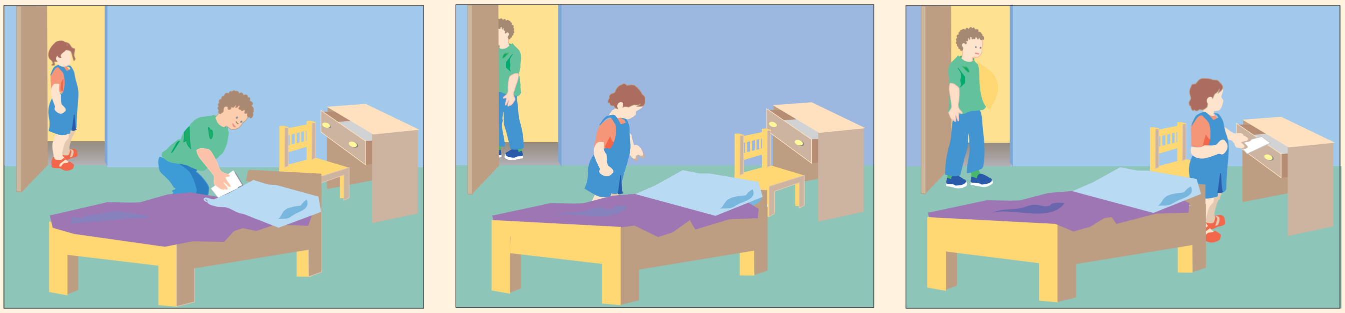
Among children of diverse cultural and SES backgrounds, false-belief understanding strengthens gradually after age 3½, becoming more secure between ages 4 and 6 (Amsterlaw & Wellman, 2006; Callaghan et al., 2005; Flynn, 2006). Mastery of false belief signals a change in representation—the ability to view beliefs as *interpretations,* not just reflections, of reality. Does this remind you of school-age children's more active view of the mind, discussed in Chapter 7? Belief–desire reasoning may mark the beginnings of this overall change.

Reasoning About Beliefs in Middle Childhood

With the realization that people can increase their knowledge by making *mental inferences* (see Chapter 7), school-age children extend false-belief understanding further. In several studies, researchers told children complex stories involving one character's belief about a second character's belief. Then the children answered questions about what the first character thought the second character would do (see Figure 11.4 on page 454). By age 6 to 7, children were aware that people form beliefs about other people's beliefs and that these *second-order beliefs* can also be wrong!

Appreciation of *second-order false belief* enables children to pinpoint the reasons that another person arrived at a certain belief (Astington, Pelletier, & Homer, 2002; Harris, 2006; Miller, 2009; Naito & Seki, 2009). Notice how it requires the ability to view a situation from at least two perspectives—that is, to reason simultaneously about what two or more people are thinking, a form of perspective taking called **recursive thought.** We think recursively when we make such statements as, "*Lisa believes* that *Jason believes* the letter is under his pillow, but that's *not what Jason really believes; he knows* the letter is in the desk."

On other complex tasks requiring recursive thought, performance also improves over middle childhood. Consider a study addressing children's appreciation of the role of people's *preexisting beliefs* in interpreting a new, ambiguous situation. School-age children listened to a story in which Cathy and Sarah see their classmate, Joan, holding a doll in front of a donation box full of toys for poor children. Cathy likes Joan. Sarah, however, dislikes Joan, believing she's a troublemaker. Children were asked how Cathy and Sarah might interpret Joan's behavior. Would they, for example, appreciate that Cathy would likely think Joan was donating the doll out of kindness, whereas Sarah would probably think she was stealing the doll? Results revealed that not until age 7 to 8 could children clearly explain how



(a)

Jason has a letter from a friend. Lisa wants to read the letter, but Jason doesn't want her to. Jason puts the letter under his pillow.

(b)

Jason leaves the room to help his mother.

(c)

While Jason is gone, Lisa takes the letter and reads it. Jason returns and watches Lisa, but Lisa doesn't see Jason. Then Lisa puts the letter in Jason's desk.

FIGURE 11.4 Example of a second-order false-belief task. After relating the story in the sequence of pictures, the researcher asks a second-order false-belief question: "Where does Lisa think Jason will look for the letter? Why?" Around age 7, children answer correctly—that Lisa thinks Jason will look under his pillow because Lisa doesn't know that Jason saw her put the letter in the desk. (Adapted from Astington, Pelletier, & Homer, 2002.)

people's prior beliefs might affect their viewpoints (Pillow, 1991). Around this age, children also grasp that two people are likely to interpret the same event—such as an ambiguous fragment removed from a larger drawing they have never seen—differently, no matter what beliefs or other biases they bring to the situation (Lalonde & Chandler, 2002). They recognize that that the same reality can be construed in many ways.

In sum, compared to younger children, school-age children have a far more sophisticated view of the mind: They regard it as an active interpreter of experience. (Return to page 303 in Chapter 7 to review a similar advance in metacognitive knowledge at about the same time.)

Social Consequences Preschoolers' capacity to use both beliefs and desires to predict people's behavior becomes a powerful tool for reflecting on thoughts and emotions and a good predictor of social skills (Harwood & Farrar, 2006; Watson et al., 1999). False-belief understanding is linked to gains in young children's capacity to discuss thoughts and feelings in conversations with friends (Hughes, Ensor, & Marks, 2010). And it predicts quality of sociodramatic play—specifically, the capacity to engage in joint planning, to negotiate pretend roles, and to imagine verbally, without the support of real objects (Jenkins & Astington, 2000). It is also associated with early reading ability, probably because it helps children comprehend story narratives (Astington & Pelletier, 2005). To follow a story line, children generally must link plot actions with characters' motives and beliefs.

Once children grasp the relation between beliefs and behavior, they apply their understanding to a wider range of situations. For example, children who pass false-belief tasks have more accurate eyewitness memories (see Chapter 7, page 300) (Templeton & Wilcox, 2000). They realize that one person can present misinformation to another, which can affect the second individual's beliefs. Consequently, in reporting observed events, such children are more likely to resist attempts to mislead them.

© LAURA DWIGHT PHOTOGRAPHY

The ability to engage in recursive thought enables these children to understand that conflicts often arise out of multiple, yet legitimate, interpretations of the same reality. This capacity leads to dramatic gains in social skills.

School-age children's capacity for recursive thought leads to further, dramatic gains in social skills. They now understand that conflicts often arise because of multiple yet legitimate interpretations of the same reality (Carpendale & Lewis, 2006). Consequently, they often call on their recursive capacity to clear up misunderstandings: "*I thought you would think* I was just kidding when I said that." They also rely on it to decide when to disguise their real thoughts and feelings: "He'll think I'm jealous if I tell him I don't like his new video game, so I'll act like I do."

As these findings illustrate, theory-of-mind development from early to middle childhood strengthens children's appreciation of the relation between their own and others' beliefs and promotes their reasoned attempts to change others' beliefs. As a result, it contributes to many social competencies.

Factors Contributing to Children's Theory of Mind How do children develop a theory of mind beginning at such a young age? Research suggests that language, executive function, make-believe play, and social experiences all contribute.

Language and Verbal Reasoning. The prefrontal cortex seems to play a crucial role in theory-of-mind development. ERP brain-wave recordings obtained while 4- to 6-year-olds reasoned about others' beliefs revealed that children who pass false-belief tasks (as opposed to those who fail) display a pattern of activity in the left prefrontal cortex similar to that of adults engaged in the same tasks (Liu et al., 2009). This left-prefrontal ERP pattern typically appears when adults reason verbally about mental concepts.

Understanding the mind requires the ability to reflect on thoughts, which language makes possible. Many studies indicate that language ability strongly predicts preschoolers' grasp of false belief (Milligan, Astington, & Dack, 2007). Children who spontaneously use, or are trained to use, complex sentences with mental-state words are especially likely to pass false-belief tasks (de Villiers & de Villiers, 2000; Hale & Tager-Flusberg, 2003). The Quechua village people of the Peruvian highlands refer to mental states such as "think" and "believe" indirectly, because their language lacks mental-state terms. Quechua children have difficulty with false-belief tasks for years after children in industrialized nations have mastered them (Vinden, 1996). In contrast, Chinese languages have verb markers that can label the word "believe" as decidedly false. When adults use those markers within false-belief tasks, Chinese preschoolers perform better (Tardif, Wellman, & Cheung, 2004).

Executive Function. Several aspects of preschoolers' executive function—ability to inhibit inappropriate responses, think flexibly, and plan—predict current performance on false-belief tasks as well as improvements over time (Hughes, 1998; Hughes & Ensor, 2007; Sabbagh et al., 2006). Like language, these cognitive skills enhance children's capacity to reflect on their experiences and mental states. Gains in inhibition, considered in Chapter 7, predict false-belief understanding particularly strongly, perhaps because false-belief tasks require suppression of an irrelevant response—the tendency to assume that others' knowledge and beliefs are the same as one's own (Birch & Bloom, 2003; Carlson, Moses, & Claxton, 2004).

Security of Attachment and Maternal "Mind-Mindedness." In longitudinal research, mothers of securely attached babies were more likely to comment appropriately on their infants' mental states: "Do you *remember* Grandma?" "You really *like* that swing." These mothers continued to describe their children, when they reached preschool age, in terms of mental characteristics: "She's got a mind of her own!" This maternal "mind-mindedness" was positively associated with early mental-state attainments, such as understanding that others may have desires discrepant from one's own, as well as later performance on false-belief and other theory-of-mind tasks (Laranjo et al., 2010; Meins et al., 1998, 2003; Ruffman et al., 2006).

Parental commentary about mental states—initially, "desire" talk ("want," "like," "wish") and, later, more advanced "think," "believe," "know" remarks—exposes infants and young children to concepts and language that help them think about their own and others' mental lives (Taumoepeau & Ruffman, 2006). Some researchers suggest that children's reflections on inner states are among the representations that make up their internal working models of close relationships (see page 430 in Chapter 10) (Reese, Newcombe, & Bird, 2006; Symons, 2004). This mental-state knowledge emerges earlier—and seems to be more objective and richer—among securely attached children, whose parents frequently refer to desires, intentions, beliefs, and emotions.

Make-Believe Play. Earlier we noted that theory of mind fosters children's sociodramatic play. But make-believe also offers a rich context for thinking about the mind. As children act out roles, they imagine and express the thoughts and emotions of the characters they portray and their implications (Kavanaugh, 2006b). These experiences may increase children's awareness that belief influences behavior. In support of this idea, preschoolers who engage in extensive fantasy role play or who have imaginary companions—and, thus, are deeply absorbed in creating make-believe characters—are advanced in understanding of false belief and other aspects of the mind (Astington & Jenkins, 1995; Lalonde & Chandler, 1995).

© IAN SHAW/ALAMY

Because this preschooler has two older siblings, she participates in more family talk about thoughts, beliefs, and emotions. Sibling interactions contribute to false-belief and other mental-state understandings.

Social Interaction. Preschoolers with siblings who are also children (but not infants)—and especially those with older siblings or with two or more siblings—tend to be more aware of false belief. Children with older siblings close in age, and those with more siblings, are exposed to—and participate in—more family talk about thoughts, beliefs, and emotions (Hughes et al., 2010; McAlister & Peterson, 2006, 2007; Symons, 2004). Similarly, preschool friends who often engage in mental-state talk are advanced in false-belief and other mental-state understandings (de Rosnay & Hughes, 2006; Hughes & Dunn, 1998).

Style of adult–child interaction also contributes. Rich conversations between parents and 2-year-olds—especially, discourse with many explanations of people's actions and with well-connected exchanges in which each speaker's remark is related to the other's previous remark—predict subsequent mastery of false belief (Ensor & Hughes, 2008; Lohmann & Tomasello, 2003). And at age 4, elaborative, well-connected parent–child conversations continue to be associated with children's theory-of-mind progress (Ontai & Thompson, 2010). References to mental states occur especially often in well-connected dialogue, which may provoke deeper insights than other forms of talk. In line with Vygotsky's theory, these interactive experiences offer children opportunities to talk about inner states, receive feedback, observe different viewpoints, and become increasingly aware of their own and others' mental activities.

Core knowledge theorists (see Chapter 6, page 261) believe that to profit from the social experiences just described, children must be biologically prepared to develop a theory of mind. They claim that children with *autism,* for whom mastery of false belief is either greatly delayed or absent, are deficient in the brain mechanism that enables humans to detect mental states. See the Biology and Environment box on the following page to find out more about the biological basis of reasoning about the mind.

LOOK and LISTEN

While observing a parent or teacher conversing with a preschool child, record features of interaction that promote false-belief and other mental-state understandings.

Self-Concept

As children develop an appreciation of their inner mental world, they think more intently about themselves. During early childhood, knowledge and evaluation of the self's characteristics expands (Harter, 2003, 2006). Children begin to construct a **self-concept,** the set of attributes, abilities, attitudes, and values that an individual believes defines who he or she is.

© LAURA DWIGHT PHOTOGRAPHY

Preschoolers' self-concepts emphasize observable characteristics and typical emotions and attitudes. If asked to describe herself, this child might say, "I like to pour my own milk!"

Early Childhood

Ask a 3- to 5-year-old to tell you about himself, and you are likely to hear something like this: "I'm Tommy. I'm 4 years old. I can wash my hair all by myself. I have a new Tinker Toy set, and I made this big, big tower." Preschoolers' self-concepts largely consist of observable characteristics, such as their name, physical appearance, possessions, and everyday behaviors (Harter, 2006; Watson, 1990).

By age 3½, children also describe themselves in terms of typical emotions and attitudes ("I'm happy when I play with my friends"; "I don't like scary TV programs;" "I usually do what Mommy says"), suggesting a beginning understanding of their unique psychological characteristics (Eder & Mangelsdorf, 1997). And by age 5, children's degree of agreement with a battery of such statements coincides with maternal reports of their personality traits, indicating that older preschoolers have a sense of their own timidity, agreeableness, and positive or negative affect (Brown et al., 2008). As further support for this emerging grasp of personality, when given a trait label ("shy," "mean"), 4-year-olds infer appropriate motives and feelings. For example, they know that a shy person doesn't like to be with unfamiliar people (Heyman & Gelman, 1999). But preschoolers do not yet say, "I'm helpful" or "I'm shy." Direct references to personality traits must wait for greater cognitive maturity.

BIOLOGY and ENVIRONMENT

"Mindblindness" and Autism

Michael stood at the water table in Leslie's classroom, repeatedly filling a plastic cup and dumping out its contents—dip-splash, dip-splash—until Leslie came over and redirected his actions. Without looking at Leslie's face, Michael moved to a new repetitive pursuit: pouring water from one cup into another and back again. As other children entered the play space and conversed, Michael hardly noticed.

Michael has *autism* (a term that means "absorbed in the self") ,the most severe behavior disorder of childhood. Like other children with autism, by age 3 he displayed deficits in three core areas of functioning. First, he had only limited ability to engage in nonverbal behaviors required for successful social interaction, such as eye gaze, facial expressions, gestures, imitation, and give-and-take. Second, his language was delayed and stereotyped. He used words to echo what others said and to get things he wanted, not to connect socially or exchange ideas. Third, he engaged in much less make-believe play than other children (Frith, 2003; Walenski, Tager-Flusberg, & Ullman, 2006). And Michael showed another typical feature of autism: His interests were narrow and overly intense. For example, one day he sat for more than an hour spinning a toy Ferris wheel.

Researchers agree that autism stems from abnormal brain functioning, usually due to genetic or prenatal environmental causes. Beginning in the first year, children with the disorder have larger-than-average brains, perhaps due to massive overgrowth of synapses and lack of synaptic pruning, which accompanies normal development of cognitive, language, and communication skills (Courchesne, Carper, & Akshoomoff, 2003).

The amygdala, especially, grows abnormally large in childhood, followed by a greater than average reduction in size in adolescence and adulthood. This deviant growth pattern is believed to contribute to deficits in emotional responsiveness and social interaction involved in the disorder (Schumann et al., 2009; Schumann & Amaral, 2010). The larger the amygdala compared with typically developing children, the more severe the child's social and communicative impairments. Furthermore, fMRI studies reveal that autism is associated with reduced activity in areas of the cerebral cortex involved in processing emotional and social information, and with weaker connections between the amygdala and the temporal lobes (important for processing facial expressions) (Monk et al., 2010; Théoret et al., 2005).

Mounting evidence reveals that children with autism have a deficient theory of mind. Long after they reach the intellectual level of an average 4-year-old, they have great difficulty with false belief. Most find it hard to attribute mental states to themselves or others (Steele, Joseph, & Tager-Flusberg, 2003). They rarely use mental-state words, such as *believe, think, know, feel,* and *pretend.*

As early as the second year, children with autism show deficits in emotional and social capacities believed to contribute to an understanding of mental life. Compared with other children, they have difficulty distinguishing facial expressions and less often establish joint attention, point to share interest in an object or event, engage in social referencing, or imitate an adult's novel behaviors (Chawarska & Shic, 2009; Mundy & Stella, 2000; Vivanti et al., 2008). And because children with autism are relatively insensitive to eye gaze as a cue to what a speaker is talking about, they often assume that another person's language refers to what they themselves are looking at—a possible reason for their frequent nonsensical expressions (Baron-Cohen, Baldwin, & Crowson, 1997).

© BOB DAEMMRICH/PHOTOEDIT

This child, who has autism, is barely aware of his teacher and classmates. His "mindblindness" might be due to a basic deficit in social awareness, a general impairment in executive function, or a deficit in holistic processing.

Do these findings indicate that autism is due to an impairment in an innate, core brain function, which leaves the child "mindblind" and therefore unable to engage in human sociability? Some researchers think so (Baron-Cohen & Belmonte, 2005; Scholl & Leslie, 2000). But others point out that individuals with mental retardation but not autism also do poorly on tasks assessing mental understanding (Yirmiya et al., 1998). This suggests that some kind of general intellectual impairment is involved.

One conjecture is that children with autism are impaired in executive function. This leaves them deficient in skills involved in flexible, goal-oriented thinking, including shifting attention to address relevant aspects of a situation, inhibiting irrelevant responses, applying strategies to hold information in working memory, and generating plans (Joseph & Tager-Flusberg, 2004; Robinson et al., 2009).

Another possibility is that children with autism display a peculiar style of information processing, preferring to process the parts of stimuli over patterns and coherent wholes (Happé & Frith, 2006). Deficits in thinking flexibly and in holistic processing of stimuli would each interfere with understanding the social world because social interaction requires quick integration of information from various sources and evaluation of alternative possibilities.

It is not clear which of these hypotheses is correct. Some research suggests that impairments in social awareness, flexible thinking, processing coherent wholes, and verbal ability contribute independently to autism (Morgan, Maybery, & Durkin, 2003; Pellicano et al., 2006). Perhaps several biologically based deficits underlie the tragic social isolation of children like Michael.

Middle Childhood Over time, children organize their observations of typical behaviors and internal states into general dispositions. A major change occurs between ages 8 and 11, as the following self-description by an 11-year-old illustrates:

> My name is A. I'm a human being. I'm a girl. I'm a truthful person. I'm not pretty. I do so-so in my studies. I'm a very good cellist. I'm a very good pianist. I'm a little bit tall for my age. I like several boys. I like several girls. I'm old-fashioned. I play tennis. I am a very good swimmer. I try to be helpful. I'm always ready to be friends with anybody. Mostly I'm good, but I lose my temper. I'm not well liked by some girls and boys. I don't know if I'm liked by boys or not. (Montemayor & Eisen, 1977, pp. 317–318).

Instead of specific behaviors, this child emphasizes competencies: "a very good cellist," "so-so in my studies" (Damon & Hart, 1988). She also describes her personality, mentioning both positive and negative traits: "truthful" but "short-tempered." Older school-age children are far less likely than younger children to describe themselves in extreme, all-or-none ways.

These evaluative self-descriptions result from school-age children's frequent **social comparisons**—judgments of their own appearance, abilities, and behavior in relation to those of others. Whereas 4- to 6-year-olds can compare their own performance to that of a single peer, older children can compare multiple individuals, including themselves (Butler, 1998; Harter, 2003, 2006). Consequently, they conclude that they are "very good" at some things, "so-so" at others, and "not good" at still others.

Adolescence In early adolescence, the self differentiates further. Teenagers mention a wider array of traits, which vary with social context—for example, self with mother, father, close friends, and romantic partner, and as student, athlete, and employee. As one young teenager commented:

> I'm an extrovert with my friends: I'm talkative, pretty rowdy, and funny. . . . With my parents, I'm more likely to be depressed. I feel sad as well as mad and also hopeless about ever pleasing them. . . . At school, I'm pretty intelligent. I know that because I'm smart when it comes to how I do in classes. I'm curious about learning new things, and I'm also creative when it comes to solving problems. . . . I can be a real introvert around people I don't know well. . . . I worry a lot about what others my age who are not my closest friends must think of me, probably that I'm a total dork. (Harter, 2006, p. 531)

Notice, also, that young adolescents unify separate traits ("smart" and "curious") into more abstract descriptors ("intelligent"). But these generalizations about the self are not interconnected and are often contradictory. For example, 12- to 14-year-olds might mention opposing traits—"intelligent" and "clueless," "extrovert" and "introvert." These disparities result from expansion of the adolescent's social world, which creates pressure to display different selves in different relationships. As adolescents' awareness of these inconsistencies grows, they frequently agonize over "which is the real me" (Harter, 1999, 2003, 2006).

From middle to late adolescence, cognitive changes enable teenagers to combine their traits into an organized system. Their use of qualifiers ("I have a *fairly* quick temper," "I'm not *thoroughly* honest") reveals their increased acceptance of situational variations in psychological qualities. Older adolescents also add integrating principles, which make sense of formerly troublesome contradictions. "I'm very adaptable," said one young person. "When I'm around my friends, who think that what I say is important, I'm talkative, but around my family I'm quiet because they're never interested enough to really listen to me" (Damon, 1990, p. 88).

Compared with school-age children, teenagers place more emphasis on social virtues, such as being friendly, considerate, kind, and cooperative—traits that reflect adolescents' increasing concern with being viewed positively by others. Among older adolescents, personal and moral values also emerge as key themes. Here is how one 17-year-old described herself:

> I'm a pretty conscientious person. . . . Eventually I want to go to law school, so developing good study habits and getting top grades are both essential. . . . I'd like to be an ethical person who treats other people fairly. . . . I don't always live up to that standard; that is, sometimes I do something that doesn't feel ethical. When that happens, I get a little depressed because I don't like myself as a person. But I tell myself that it's natural to make mistakes, so I don't really question the fact that deep down inside, the real me is a moral person. (Harter, 2006, pp. 545–546)

LOOK and LISTEN

Pose the following question to a 12- to 14-year-old and a 16- to 18-year-old: "What are you like as a person?" Do differences in their self-descriptions match research findings on development of self-concept?

This well-integrated account differs from the fragmented, listlike self-descriptions typical of children. As adolescents revise their views of themselves to include enduring beliefs and plans, they move toward the kind of unity of self that is central to identity development.

Cognitive, Social, and Cultural Influences on Self-Concept

What factors account for these revisions in self-concept? Cognitive development certainly affects the changing *structure* of the self. School-age children, as we saw in Chapter 6, can better coordinate several aspects of a situation in reasoning about their physical world. Similarly, in the social realm, they combine typical experiences and behaviors into stable psychological dispositions, blend positive and negative characteristics, and compare their own characteristics with those of many peers (Harter, 2006). And formal operational thought transforms the adolescent's vision of the self into a complex, well-organized, internally consistent picture (Harter, 1999, 2003).

The changing *content* of the self is a product of both cognitive capacities and feedback from others. Sociologist George Herbert Mead (1934) described the self as a **generalized other**—a blend of what we imagine important people in our lives think of us. He proposed that a psychological self emerges when children adopt a view of the self that resembles others' attitudes toward the child. Mead's ideas indicate that perspective-taking skills—in particular, an improved ability to infer what other people are thinking—are crucial for developing a self-concept based on personality traits. During middle childhood and adolescence, young people become better at "reading" messages they receive from others. And as school-age children internalize others' expectations, they form an *ideal self* that they use to evaluate their real self. As we will see shortly, a large discrepancy between the two can greatly undermine self-esteem, leading to sadness, hopelessness, and depression.

Parental support contributes vitally to the clarity and optimism of children's self-concepts. In one study, the richness of mothers' emotional communication in narratives about the past—evaluations of positive events and explanations of children's negative feelings and their resolution ("Talking about your teacher moving away helped you feel better")—predicted greater consistency in 5- and 6-year-olds' reports of their personal characteristics (Bird & Reese, 2006). And school-age children with a history of elaborative parent–child conversations construct more positive, detailed personal narratives and thus have more complex, favorable, and coherent self-images (Harter, 2006).

In middle childhood, children also look to more people beyond the family for information about themselves as they enter a wider range of settings in school and community. And self-descriptions now include frequent references to social groups: "I'm a Boy Scout, a paper boy, and a Prairie City soccer player," remarked one 10-year-old. Gradually, as children move into adolescence, their sources of self-definition become more selective. Although parents and teachers remain influential, self-concept becomes increasingly vested in feedback from close friends (Oosterwegel & Oppenheimer, 1993).

Keep in mind, however, that the content of self-concept varies from culture to culture. In earlier chapters, we noted that Asian parents stress harmonious interdependence, Western parents separateness and self-assertion (Markus & Kitayama, 1991). Turn back to the Cultural Influences box on page 451, and notice this difference in parents' personal storytelling with their young children. These contrasting values are apparent in school-age children's self-concepts. When asked to recall personally significant past experiences (their last birthday, a time their parent scolded them), U.S. children gave longer accounts including more personal preferences, skills, and opinions. Chinese children, in contrast, more often referred to social interactions and to others. Similarly, in their self-descriptions, U.S. children listed more personal attributes ("I'm smart," "I like hockey"), Chinese children more attributes involving group membership and relationships ("I belong to the Lee family," "I'm in second grade," "I like to help my mom wash dishes") (Wang, 2004, 2006b).

© MICHAEL NEWMAN/PHOTOEDIT

As school-age children spend more time away from home, their self-descriptions increasingly refer to social groups—for example, "I'm a member of our school's cooking club!"

Milestones

Emergence of Self and Development of Self-Concept

AGE	MILESTONES
1–2 years	Awareness of self as physically distinct from surroundings increases. Recognizes image of self and, by end of this period, uses own name or personal pronoun to refer to self. Constructs explicit body self-awareness, and scale errors decline.
3–5 years	Forms a categorical self by classifying the self and others on the basis of perceptually distinct attributes (age, gender, physical characteristics), goodness and badness, and competencies. Constructs a remembered self, in the form of a life-story narrative. Desire theory of mind expands into a belief–desire theory, as indicated by understanding of false belief. Forms a self-concept consisting of observable characteristics and typical emotions and attitudes.
6–10 years	Appreciates second-order false beliefs and the role of preexisting beliefs in interpreting a new, ambiguous situation—attainments reflecting capacity to engage in recursive thought. Emphasizes personality traits and both positive and negative attributes in self-concept. Makes social comparisons among multiple individuals.
11 years and older	Unifies separate traits, such as "smart" and "talented," into more abstract descriptors, such as "intelligent," in self-concept. Combines traits making up self-concept into an organized system.

Note: These milestones represent overall age trends. Individual differences exist in the precise age at which each milestone is attained.

Finally, although school-age children from diverse cultures view themselves as more knowledgeable about their own inner attributes than significant adults, Japanese children attribute considerably greater knowledge to parents and teachers than American children do (Mitchell et al., 2010). Perhaps because of their more interdependent self, Japanese children are more likely to assume that people share common understandings and that, therefore, their inner states are more transparent to others.

In sum, in characterizing themselves, children from individualistic cultures seem to be more egoistic and competitive, those from collectivist cultures more concerned with connections to others—a finding that underscores the powerful impact of the social environment on self-concept. The Milestones table above summarizes the vast changes in the self from infancy through adolescence.

ASK YOURSELF

Review ■ How does cognitive development affect changes in self-concept from early childhood to adolescence?

Connect ■ Recall from Chapter 6 (page 246) that between ages 4 and 8, children figure out who is really behind the activities of Santa Claus and the Tooth Fairy, and they realize that magicians use trickery. How might these understandings be related to their developing theory of mind?

Apply ■ Suggest ways that parents can promote a sturdy sense of self in infants and toddlers.

Self-Esteem: The Evaluative Side of Self-Concept

- Discuss development of and influences on self-esteem from early childhood through adolescence.
- Discuss achievement-related attributions, and suggest ways to foster a mastery-oriented approach in children.

So far, we have focused on how the general structure and content of self-concept change with age. Another component of self-concept is **self-esteem,** the judgments we make about our own worth and the feelings associated with those judgments. High self-esteem implies a realistic evaluation of the self's characteristics and competencies, coupled with an attitude of self-acceptance and self-respect.

Self-esteem ranks among the most important aspects of self-development because evaluations of our own competencies affect emotional experiences, future behavior, and long-term psychological adjustment. As soon as a categorical self with features that can be judged positively or negatively is in place, children become self-evaluative beings. Around age 2, they call a parent's attention to an achievement, such as completing a puzzle, by pointing and saying something like "Look, Mom!" In addition, 2-year-olds are likely to smile when they succeed at a task an adult set for them and to look away or frown when they fail (Stipek, Recchia, & McClintic, 1992). Self-esteem originates early, and its structure becomes increasingly elaborate with age.

The Structure of Self-Esteem

TAKE A MOMENT... Think about your own self-esteem. Besides a global appraisal of your worth as a person, do you have an array of separate self-judgments concerning how well you perform at different activities?

Researchers have studied the multifaceted nature of self-esteem by applying *factor analysis* (see page 321 in Chapter 8) to children's ratings of the extent to which statements like these are true: "I am good at homework." "I'm usually the one chosen for games." "Most kids like me." By age 4, preschoolers have several self-judgments—for example, about learning things in school, making friends, getting along with parents, and feeling physically attractive (Marsh, Ellis, & Craven, 2002). Compared with that of older children, however, their understanding is limited.

The structure of self-esteem depends on evaluative information available to children and their ability to process that information. Around age 6 to 7, children in diverse Western cultures have formed at least four broad self-evaluations: academic competence, social competence, physical/athletic competence, and physical appearance. Within these are more refined categories that become increasingly distinct with age (Marsh, 1990; Marsh & Ayotte, 2003; Van den Bergh & De Rycke, 2003). Furthermore, the capacity to view the self in terms of stable dispositions enables school-age children to combine their separate self-evaluations into a general psychological image of themselves—an overall sense of self-esteem (Harter, 2003, 2006). Consequently, self-esteem takes on the hierarchical structure shown in Figure 11.5 on page 462.

Children attach greater importance to certain self-judgments, giving them more weight in the total picture. Although individual differences exist, during childhood and adolescence perceived physical appearance correlates more strongly with global self-esteem than any other self-esteem factor (Klomsten, Skaalvik, & Espnes, 2004; Shapka & Keating, 2005). Emphasis on appearance—in the media, among peers, and in society—has major implications for overall satisfaction with the self.

The arrival of adolescence adds several new dimensions of self-esteem—close friendship, romantic appeal, and job competence—that reflect important concerns of this period (Harter, 1999, 2003, 2006). Furthermore, adolescents become more discriminating in the people to whom they look for validation of their self-esteem. Some rely more on parents, others more on teachers, and still others more on peers—differences that reflect the extent to which teenagers believe that people in each context are interested in and respect them as individuals (Harter, Waters, & Whitesell, 1998).

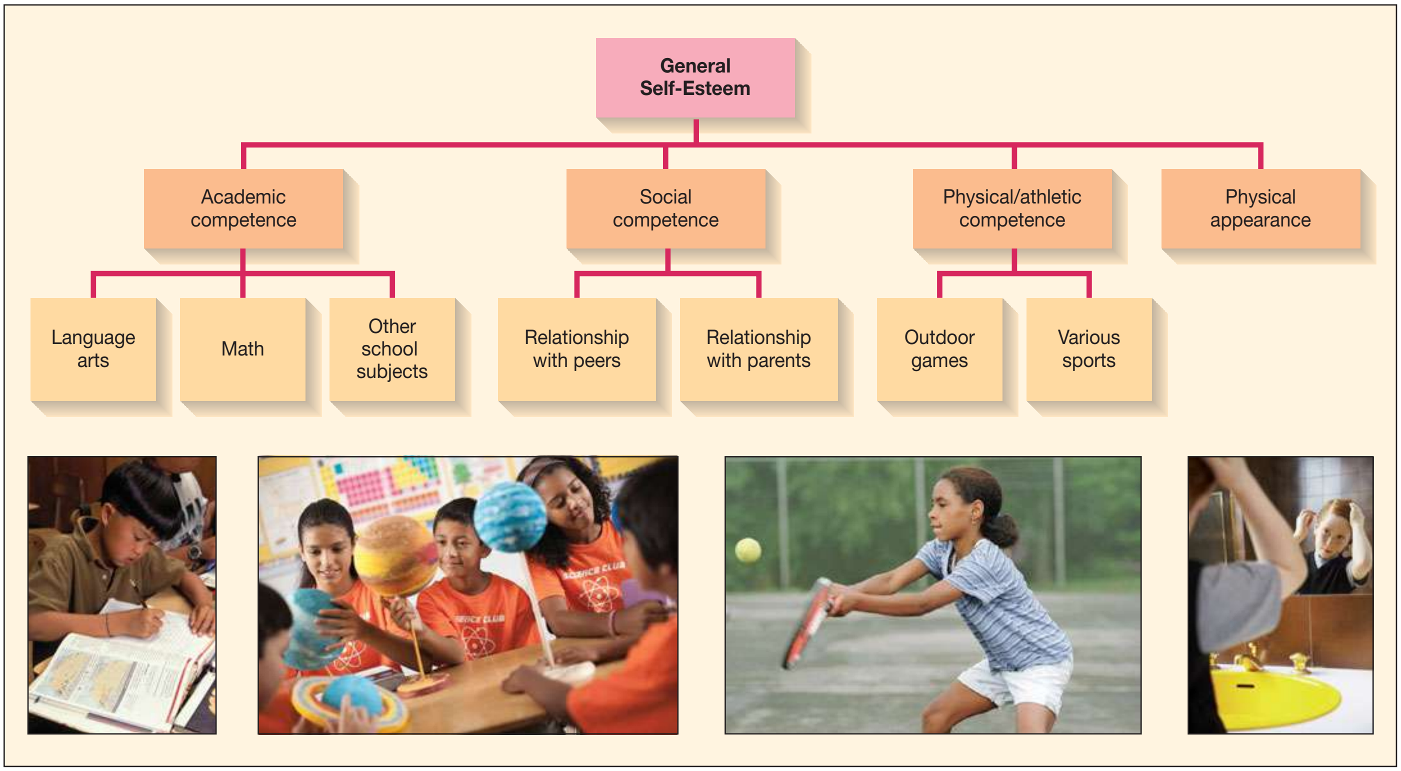

FIGURE 11.5 **Hierarchical structure of self-esteem in the mid-elementary school years.** From their experiences in different settings, school-age children form at least four separate self-esteems: academic competence, social competence, physical/athletic competence, and physical appearance. These differentiate into additional self-evaluations and combine to form a general sense of self-esteem. *Photos:* (far left) © Mary Kate Denny/PhotoEdit; (middle left) © Tim Pannell/CORBIS; (middle right) © Mitch Wojnarowicz/The Image Works; (far right) Radius Images/Photolibrary

Changes in Level of Self-Esteem: The Role of Social Comparisons

Because preschoolers have trouble distinguishing between their desired and their actual competence, they usually rate their own ability as extremely high and underestimate task difficulty (Harter, 2003, 2006). In early childhood, high self-esteem is adaptive, contributing greatly to preschoolers' initiative during a period in which they must master many new skills.

Self-esteem declines over the first few years of elementary school as children evaluate themselves in various areas (Marsh, Craven, & Debus, 1998; Wigfield et al., 1997). This decline occurs as children receive more competence-related feedback, as their performances are increasingly judged in relation to those of others, and as they become cognitively capable of social comparison.

To protect their self-esteem, most children eventually balance social comparisons with personal achievement goals (Ruble & Flett, 1988). Perhaps for this reason, the drop in self-esteem in the early school years is seldom harmful. Then, from fourth grade on, self-esteem rises and remains high for the majority of young people, who feel especially good about their peer relationships and athletic capabilities (Cole et al., 2001; Impett et al., 2008; Twenge & Campbell, 2001). The main exception is a decline in self-worth for some adolescents after transition to middle and high school. Entry into a new school, accompanied by new teacher and peer expectations, may temporarily interfere with the ability to make realistic judgments about behavior and performance. In Chapter 15, we will examine these school transition effects. For most young people, however, becoming an adolescent leads to feelings of pride and self-confidence.

Influences on Self-Esteem

From middle childhood to adolescence, individual differences in self-esteem become increasingly stable (Trzesniewski, Donnellan, & Robins, 2003). And positive relationships among self-esteem, valuing of various activities, and success at those activities emerge and strengthen with age. For example, academic self-esteem is a powerful predictor of young people's judgments of the importance and usefulness of school subjects, willingness to exert effort, achievement, and eventual career choice (Denissen, Zarrett, & Eccles, 2007; Valentine, DuBois, & Cooper, 2004; Whitesell et al., 2009). Children and adolescents with high social self-esteem are consistently better-liked by their peers (Jacobs et al., 2002). And as we saw in Chapter 5, sense of athletic competence is positively associated with investment in and performance at sports.

Furthermore, across age, sex, SES, and ethnic groups, individuals with mostly favorable self-esteem profiles tend to be well-adjusted, sociable, and conscientious. In contrast, low self-esteem in all areas is linked to a wide array of adjustment difficulties (DuBois et al., 1999; Kim & Cicchetti, 2006; Robins et al., 2001). But certain self-esteem factors are more strongly related to adjustment. Adolescents who feel highly dissatisfied with parental relationships often are aggressive and antisocial. Those with poor academic self-esteem tend to be anxious and unfocused. And those who view their peer relationships negatively are likely to be anxious and depressed (Marsh, Parada, & Ayotte, 2004; Rudolph, Caldwell, & Conley, 2005). And although virtually all teenagers become increasingly concerned about others' opinions, those who are overly dependent on social approval place their self-esteem continually "on the line." As a result, they report frequent self-esteem shifts—on average, about once a week (Harter & Whitesell, 2003). Let's take a closer look at factors that affect self-esteem—both its level and its stability.

© DAVID R. FRAZIER/THE IMAGE WORKS

During adolescence, self-esteem typically rises, fostered by pride in new competencies and growing self-confidence. This teenager beams as she displays the blue ribbon she won at an agricultural fair.

Culture As with self-concept, cultural forces profoundly affect self-esteem. An especially strong emphasis on social comparison in school may underlie the finding that despite their higher academic achievement, Chinese and Japanese children score lower than U.S. children in self-esteem—a difference that widens with age (Harter, 2006; Hawkins, 1994; Twenge & Crocker, 2002). In Asian classrooms, competition is tough, and achievement pressure is high. At the same time, because their culture values modesty and social harmony, Asian children rely less on social comparisons to promote their own self-esteem. Rather, they tend to be reserved about judging themselves positively but generous in their praise of others (Falbo et al., 1997).

Gender-stereotyped expectations also affect self-esteem. In one study, the more 5- to 8-year-old girls talked with friends about the way people look, watched TV shows focusing on physical appearance, and perceived their friends as valuing thinness, the greater their dissatisfaction with their physical self and the lower their overall self-esteem a year later (Dohnt & Tiggemann, 2006). By adolescence, girls feel less confident than boys about their physical appearance and athletic abilities. With respect to academic self-esteem, boys, again, are somewhat advantaged: Whereas girls score higher in language arts self-esteem, boys have higher math, science, and physical/athletic self-esteem—even when children of equal skill levels are compared (Fredericks & Eccles, 2002; Jacobs et al., 2002; Kurtz-Costes et al., 2008). At the same time, girls exceed boys in self-esteem dimensions of close friendship and social acceptance.

Although only a slight difference exists between boys and girls in overall self-esteem, a widely held assumption is that boys' overall sense of self-worth is much higher than girls' (Marsh & Ayotte, 2003; Young & Mroczek, 2003). Girls may think less well of themselves because they internalize this negative cultural message.

© SYRACUSE NEWSPAPERS/M. GREENLAR/THE IMAGE WORKS

An 11-year-old performs a traditional African dance at a community Kwanzaa celebration. A stronger sense of ethnic pride may contribute to African-American children's higher self-esteem relative to their Caucasian agemates.

Compared with their Caucasian agemates, African-American children tend to have slightly higher self-esteem, perhaps because of warm extended families and a stronger sense of ethnic pride (Gray-Little & Hafdahl, 2000). Finally, children and adolescents who attend schools or live in neighborhoods where their SES and ethnic groups are well-represented feel a stronger sense of belonging and have fewer self-esteem problems (Gray-Little & Carels, 1997).

Child-Rearing Practices Children and adolescents whose parents are warm and accepting, provide reasonable expectations for mature behavior, and engage in positive problem solving (resolve conflicts by collaborating with the child on a solution) feel especially good about themselves (Lindsey et al., 2008; McKinney, Donnelly, & Renk, 2008; Wilkinson, 2004). Warm, positive parenting lets young people know that they are accepted as competent and worthwhile. And firm but appropriate expectations, backed up with explanations, help them make sensible choices and evaluate themselves against reasonable standards.

© DAN SMETZER/PHOTOEDIT

Parental warmth and acceptance combined with firm but appropriate expectations help children develop a positive, realistic sense of self-esteem.

Controlling parents—those who too often help or make decisions for their child—communicate a sense of inadequacy to children. Having parents who are repeatedly disapproving and insulting is also linked to low self-esteem (Kernis, 2002; Pomerantz & Eaton, 2000). Children subjected to such parenting need constant reassurance, and many rely heavily on peers to affirm their self-worth—a risk factor for adjustment difficulties, including aggression, antisocial behavior, and delinquency (Donnellan et al., 2005).

In contrast, overly tolerant, indulgent parenting is linked to unrealistically high self-esteem, which also undermines development. These children—whom researchers label *narcissistic* because they combine an inflated sense of superiority with obsessive worry about what others think of them—are vulnerable to temporary, sharp drops in self-esteem when their overblown self-images are challenged (Thomaes et al., 2010). They tend to lash out at peers who express disapproval and display adjustment problems, including meanness and aggression (Hughes, Cavell, & Grossman, 1997; Thomaes et al., 2008).

American cultural values have increasingly emphasized a focus on the self that may lead parents to indulge children and boost their self-esteem too much. The self-esteem of U.S. youths rose sharply from the 1970s to the 1990s—a period in which much popular parenting literature advised promoting children's self-esteem (Twenge & Campbell, 2001). Yet compared with previous generations, U.S. youths are achieving less well and displaying more antisocial behavior and other adjustment problems (Berk, 2005). Research confirms that children do not benefit from compliments ("You're terrific") that have no basis in real attainment (Damon, 1995). Rather, the best way to foster a positive, secure self-image is to encourage children to strive for worthwhile goals. Over time, a bidirectional relationship emerges: Achievement fosters self-esteem, which contributes to further effort and gains in performance (Gest, Domitrovich, & Welsh, 2005; Marsh et al., 2005).

What can adults do to promote, and to avoid undermining, this mutually supportive relationship between motivation and self-esteem? Some answers come from research on the precise content of adults' messages to children in achievement situations.

Achievement-Related Attributions

Attributions are our common, everyday explanations for the causes of behavior—our answers to the question "Why did I or another person do that?" We group the causes of our own and others' behavior into two broad categories: external, environmental causes and internal, psychological causes. Then we further divide psychological causes into two types: *ability* and *effort*. In assigning a cause, we use certain rules: If a behavior occurs for many people but only in a single situation (for example, the whole class gets A's on Mrs. Apple's French test), we conclude that it is externally caused (the test was easy). In contrast, if an individual displays a behavior in many situations (Sally always gets A's on French tests), we judge the behavior to be internally caused—by ability, effort, or both (Sally is smart and works hard).

In Chapter 8, we showed that although intelligence predicts school achievement, the relationship is far from perfect. Individual differences in **achievement motivation**—the tendency to persist at challenging tasks—are just as important. Today, researchers regard achievement-related attributions as the main reason some children display initiative when faced with obstacles to success, whereas others give up easily.

Emergence of Achievement-Related Attributions Around age 3, children begin making attributions about their successes and failures. These attributions affect their *expectancies of success,* which influence their willingness to try hard in the future.

Many studies show that preschoolers are "learning optimists" who rate their own ability very high, often underestimate task difficulty, and hold positive expectancies of success. When asked to react to a situation in which one person does worse on a task than another, young children indicate that the lower-scoring person can still succeed if she keeps on trying (Schuster, Ruble, & Weinert, 1998). Cognitively, preschoolers cannot yet distinguish the precise causes of their successes and failures. Instead, they view all good things as going together: A person who tries hard is also a smart person who is going to succeed.

Nevertheless, by age 3, some children give up easily when faced with a challenge, expressing shame and despondency after failing. These nonpersisters have a history of parental criticism of their worth and performance and of excessive control—frequent parental commands and intrusive attempts to take over when the child attempts a challenging task (Kelley, Brownell, & Campbell, 2000; Moorman & Pomerantz, 2008). In contrast, their enthusiastic, highly motivated agemates have parents who patiently support the child's initiative ("Why don't you try the next one on your own?") while offering information about how to succeed.

© CORBIS PREMIUM RF/ALAMY

Most preschoolers are "learning optimists" who believe they can succeed if they keep trying. Their attributions support initiative in the face of challenging tasks.

Furthermore, when preschool nonpersisters use dolls to act out an adult's reaction to failure, they anticipate disapproval—saying, for example, "He's punished because he can't do the puzzle." Persisters say, "He worked hard but just couldn't finish. He wants to try again" (Burhans & Dweck, 1995). Preschoolers readily internalize adult evaluations. Whereas persisters view themselves as "good," nonpersisters see themselves as "bad" (Heyman, Dweck, & Cain, 1992). Already, nonpersisters seem to base their self-esteem entirely on others' judgments, not on inner standards. Consequently, they show early signs of maladaptive achievement behaviors that become more common during middle childhood.

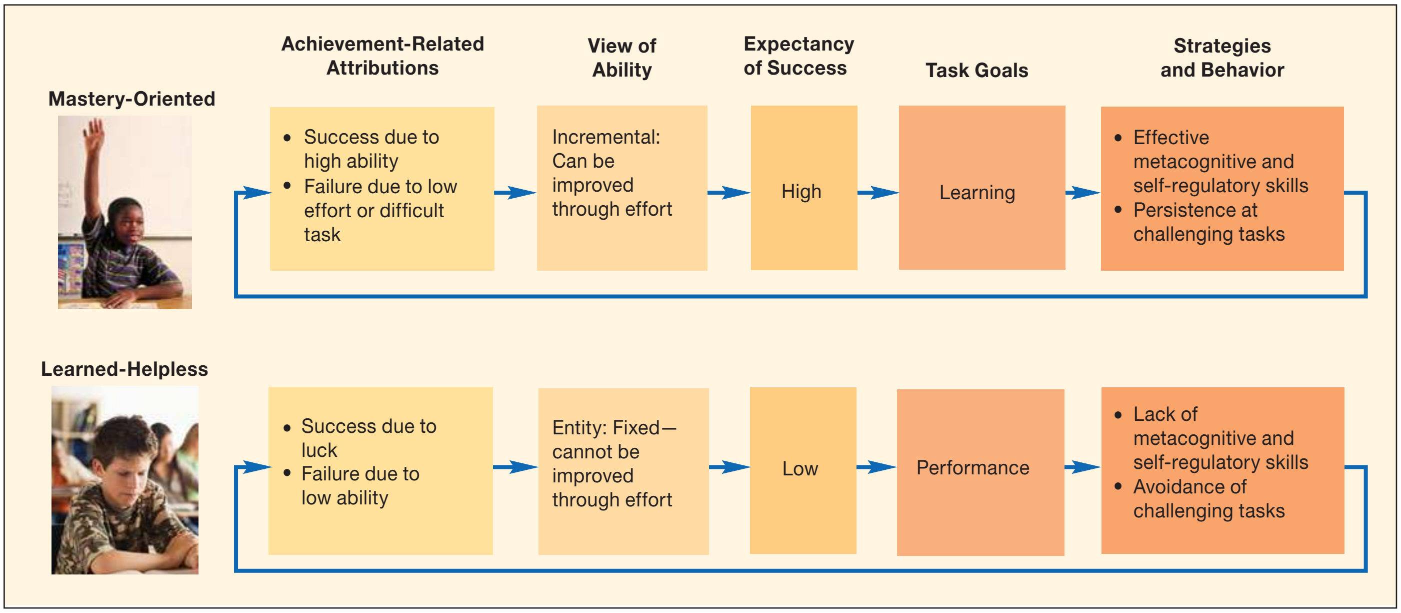
Mastery-Oriented versus Learned-Helpless Children As a result of improved reasoning skills and frequent evaluative feedback, school-age children gradually become able to distinguish ability, effort, and external factors in explaining their performance (Dweck, 2002). Those who are high in achievement motivation make **mastery-oriented attributions,** crediting their successes to ability—a characteristic they can improve through trying hard and can count on when faced with new challenges. This **incremental view of ability**—that it can increase through effort—influences the way mastery-oriented children interpret negative events. They attribute failure to factors that can be changed or controlled, such as insufficient effort or a difficult task (Heyman & Dweck, 1998). Whether these children succeed or fail, they take an industrious, persistent approach to learning.

© ALEX MARES-MANTON/GETTY IMAGES/ASIA IMAGES

Mastery-oriented children credit their successes to ability, and they seek information on how to increase their ability through effort. As a result, they approach challenging tasks with determination and persistence.

In contrast, children who develop **learned helplessness** attribute their failures, not their successes, to ability. When they succeed, they are likely to conclude that external events, such as luck, are responsible. Unlike their mastery-oriented counterparts, they hold an **entity view of ability**—that it cannot be improved by trying hard (Cain & Dweck, 1995). When a task is difficult, these children experience an anxious loss of control. They give up without really trying.

Children's attributions affect their goals. Mastery-oriented children focus on *learning goals*—seeking information on how best to increase their ability through effort.



Achievement-Related Attributions
View of Ability
Expectancy of Success
Task Goals
Strategies and Behavior
Mastery-Oriented
• Success due to high ability
• Failure due to low effort or difficult task
Incremental: Can be improved through effort
High
Learning
• Effective metacognitive and self-regulatory skills
• Persistence at challenging tasks
Learned-Helpless
• Success due to luck
• Failure due to low ability
Entity: Fixed—cannot be improved through effort
Low
Performance
• Lack of metacognitive and self-regulatory skills
• Avoidance of challenging tasks

Hence, their performance increases over time (Blackwell, Trzesniewski, & Dweck, 2007). In contrast, learned-helpless children focus on *performance goals*—obtaining positive and avoiding negative evaluations of their fragile sense of ability. Over time, learned-helpless children's ability no longer predicts how well they do. In one study, the more fourth to sixth graders held self-critical attributions, the lower they rated their competence, the less they knew about effective study strategies, the more they avoided challenge, and the poorer their academic performance. These outcomes strengthened their entity view of ability (Pomerantz & Saxon, 2001). Because learned-helpless children fail to connect effort with success, they do not develop the metacognitive and self-regulatory skills necessary for high achievement (see Chapter 7). Lack of effective learning strategies, reduced persistence, low performance, and a sense of loss of control sustain one another in a vicious cycle (Chan & Moore, 2006).

In adolescence, young people attain a fully differentiated understanding of the relationship between ability and effort. They realize that people who vary in ability can achieve the same outcome with different degrees of effort (Butler, 1999). When adolescents view their own ability as fixed and low, they conclude that mastering a challenging task is not worth the cost—extremely high effort. To protect themselves from painful feelings of failure, these learned-helpless young people select less demanding courses and careers. As Figure 11.6 shows, learned helplessness prevents children from realizing their potential.

Influences on Achievement-Related Attributions

What accounts for the different attributions of mastery-oriented and learned-helpless children? As with preschoolers, adult communication plays a key role. When parents hold an entity view of ability, their children's self-evaluations and school grades conform more closely to parental ability judgments than do those of children whose parents deny that ability is fixed (Pomerantz & Dong, 2006). Parents who believe that little can be done to improve ability may ignore information that is inconsistent with their perceptions, giving their child little opportunity to counteract a negative parental evaluation.

Indeed, children with a learned-helpless style often have parents who believe that their child is not very capable and must work much harder than others to succeed. When the child fails, the adult might say, "You can't do that, can you? It's OK if you quit" (Hokoda & Fincham, 1995). After the child succeeds, the parent might offer feedback evaluating the child's traits ("You're so smart"). Trait statements—even when positive—encourage children

LOOK and LISTEN

Observe a school-age child working on a challenging homework assignment under the guidance of a parent or other adult. What features of the adult's communication likely foster mastery-oriented attributions? How about learned helplessness?

to adopt an entity view of ability, leading them to question their competence in the face of setbacks and to retreat from challenge (Mueller & Dweck, 1998).

Teachers' messages also affect children's attributions. Teachers who attribute children's failures to effort, who are caring and helpful, and who emphasize learning goals tend to have mastery-oriented students (Anderman et al., 2001; Daniels, Kalkman, & McCombs, 2001; Natale et al., 2009). In a study of 1,600 third to eighth graders, students who viewed their teachers as providing positive, supportive learning conditions worked harder and participated more in class—factors that predicted high achievement, which sustained children's belief in the value of effort. In contrast, students with unsupportive teachers regarded their performance as externally controlled (by their teachers or by luck). This attitude predicted withdrawal from learning activities and declining achievement—outcomes that led children to doubt their ability (Skinner, Zimmer-Gembeck, & Connell, 1998).

For some children, performance is especially likely to be undermined by adult feedback. Despite their higher achievement, girls more often than boys attribute poor performance to lack of ability. Girls tend to receive messages from teachers and parents that their ability is at fault when they do not do well, and negative stereotypes (for example, that girls are weak at math) reduce their interest and effort (Bleeker & Jacobs, 2004; Cole et al., 1999). And low-SES, ethnic-minority children often receive less favorable feedback from teachers, especially when assigned to homogeneous groups of poorly achieving students in school—conditions that result in a drop in academic self-esteem and achievement (Harris & Graham, 2007; Ogbu, 1997).

Finally, cultural values affect the likelihood that children will develop learned helplessness. Asian parents and teachers are more likely than their American counterparts to hold an incremental view of ability and to view trying hard as a moral responsibility—messages they transmit to children (Mok, Kennedy & Moore, 2011; Pomerantz, Ng, & Wang, 2008). Furthermore, because of the high value their culture places on self-improvement, Asians attend more to failure than to success because failure indicates where corrective action is needed. Americans, in contrast, focus more on success because it enhances self-esteem. Observations of U.S. and Chinese mothers' responses to their fourth- and fifth-graders' puzzle solutions revealed that the U.S. mothers offered more praise after success, whereas the Chinese mothers more often pointed out the child's inadequate performance. And regardless of success or failure, Chinese mothers made more task-relevant statements aimed at ensuring that children exerted sufficient effort to do well ("You concentrated on it"; "You only got 6 out of 12") (see Figure 11.7). When children continued with the task after mothers left the room, the Chinese children showed greater gains in performance (Ng, Pomerantz, & Lam, 2007).

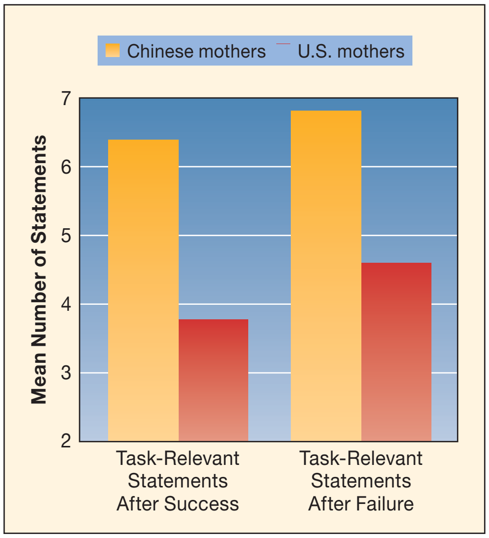

FIGURE 11.7 **Chinese and U.S. mothers' task-relevant statements in response to their fourth-grade child's success or failure on puzzle tasks.** Observations revealed that regardless of whether their child had just succeeded or failed, Chinese mothers were more likely than U.S. mothers to make task-relevant statements aimed at ensuring that the child exerted high effort. (Adapted from Ng, Pomerantz, & Lam, 2007.)

Fostering a Mastery-Oriented Approach Attribution research suggests that well-intended messages from adults sometimes undermine children's competence. An intervention called **attribution retraining** encourages learned-helpless children to believe that they can overcome failure by exerting more effort. Children are given tasks difficult enough that they will experience some failure, followed by repeated feedback that helps them revise their attributions: "You can do it if you try harder." After they succeed, children receive additional feedback—"You're really good at this"; "You really tried hard on that one"—so that they attribute their success to both ability and effort, not chance. Another approach is to encourage low-effort students to focus less on grades, more on mastering a task for its own sake, and more on individual performance improvement than on comparisons with classmates (Hilt, 2004; Horner & Gaither, 2004; Yeh, 2010). Instruction in effective strategies and cognitive self-regulation is also vital, to compensate for development lost in this area and to ensure that renewed effort pays off (Borkowski & Muthukrisna, 1995; Wigfield et al., 2006).

Attribution retraining is most effective when begun early, before children's views of themselves become hard to change. School-age children with low academic self-esteem whose parents regularly used mastery-oriented practices while helping with homework had gained in sense of academic competence,

APPLYING WHAT WE KNOW

Fostering a Mastery-Oriented Approach to Learning

CONTEXT	STRATEGIES
Provision of tasks	Select tasks that are meaningful, responsive to a diversity of pupil interests, and appropriately matched to current competence so the child is challenged but not overwhelmed.
Parent and teacher encouragement	Communicate warmth, confidence in the child's abilities, the value of achievement, and the importance of effort in success. Model high effort in overcoming failure. (For teachers) Communicate often with parents, suggesting ways to foster children's effort and progress. (For parents) Monitor schoolwork; provide scaffolded assistance that promotes knowledge of effective strategies and cognitive self-regulation.
Performance evaluations	Make evaluations private; avoid publicizing success or failure through wall posters, stars, privileges to "smart" children, and prizes for "best" performance. Emphasize individual progress and self-improvement.
School environment	Offer small classes, which permit teachers to provide individualized support for mastery. Provide for cooperative learning and peer tutoring, in which children assist one another; avoid ability grouping, which makes evaluations of children's progress public. Accommodate individual and cultural differences in styles of learning. Create an atmosphere that values academics and sends a clear message that all students can learn.

willingness to try hard on difficult tasks, and positive emotion six months later (Pomerantz, Ng, & Wang, 2006). The strategies summarized in Applying What We Know above are helpful in preventing learned helplessness. Consult the Milestones table on the following page for an overview of development of self-esteem.

ASK YOURSELF

Review ■ Describe and explain changes in the structure and level of self-esteem from early childhood to adolescence.

Connect ■ What cognitive changes support the transition to a self-concept emphasizing competencies, personality traits, and social comparisons? (*Hint:* See page 283 in Chapter 7.)

Apply ■ Should parents try to promote children's self-esteem by telling them they're "smart" or "wonderful"? Are children harmed if they do not feel good about everything they do? Why or why not?

Reflect ■ Recall your own attributions for academic successes and failures when you were in elementary school. What are those attributions like now? What messages from others may have contributed to your attributions?

▶ Describe the four identity statuses, along with factors affecting identity development.

Constructing an Identity: Who Should I Become?

Adolescents' well-organized self-descriptions and differentiated sense of self-esteem provide the cognitive foundation for forming an **identity,** first recognized by psychoanalyst Erik Erikson (1950, 1968) as a major personality achievement and a crucial step toward becoming

Milestones

Development of Self-Esteem

AGE	MILESTONES
1–2 years	• Expressions of pleasure in mastery are evident. • Sensitivity to adults' evaluations appears.
3–5 years	• Self-esteem is typically high and consists of several separate self-evaluations. • Achievement-related attributions appear but are undifferentiated; for example, a person who tries hard is smart and will succeed.
6–10 years	• Self-esteem becomes hierarchically organized; separate self-evaluations (academic, social, and physical/athletic competence, physical appearance) are integrated into an overall sense of self-esteem. • As children receive competence-related feedback and make social comparisons, self-esteem declines but then rises. • Achievement-related attributions differentiate into ability, effort, and external factors.
11 years–adulthood	• New dimensions of self-esteem are added (close friendship, romantic appeal, job competence). • Self-esteem continues to rise. • Achievement-related attributions reflect full differentiation of ability and effort.

Note: These milestones represent overall age trends. Individual differences exist in the precise age at which each milestone is attained.

a productive, content adult. Constructing an identity involves defining who you are, what you value, and the directions you choose to pursue in life. One expert described it as an explicit theory of oneself as a rational agent—one who acts on the basis of reason, takes responsibility for those actions, and can explain them (Moshman, 2005). This search for what is true and real about the self drives many choices—vocation, interpersonal relationships, community involvement, ethnic-group membership, and expression of one's sexual orientation, as well as moral, political, and religious ideals.

Erikson believed that successful psychosocial outcomes of infancy and childhood pave the way toward a coherent, positive identity. (Return to Chapter 1, page 16, to review Erikson's stages.) Although the seeds of identity formation are planted early, not until late adolescence and emerging adulthood do young people become absorbed in this task. According to Erikson, in complex societies teenagers experience an *identity crisis*—a temporary period of distress as they experiment with alternatives before settling on values and goals. They go through a process of inner soul-searching, sifting through characteristics that defined the self in childhood and combining them with emerging traits, capacities, and commitments. Then they mold these into a solid inner core that provides a sense of sameness as they move through different roles in daily life. Once formed, identity continues to be refined throughout life as people reevaluate earlier commitments and choices.

Current theorists agree with Erikson that questioning of values, plans, and priorities is necessary for a mature identity, but they no longer describe this process as a "crisis" (Kroger, 2005). In fact, Erikson himself did not believe that adolescents' inner struggle need be severe to arrive at a clear, unified identity (Côté, 2009). For most young people, identity development is not traumatic or disturbing but, rather, a process of *exploration* followed by *commitment.* As young people try out life possibilities, they gather important information about themselves and their environment and gradually move toward making enduring decisions. In the process, they forge an organized self-structure (Arnett, 2000, 2006; Moshman, 2005).

Erikson described the negative outcome of adolescence as *identity confusion.* If young people's earlier conflicts were resolved negatively or if society limits their choices to ones that do not match their abilities and desires, they may appear shallow, directionless, and unprepared for the psychological challenges of adulthood. In the following sections, we will see that young people go about the task of defining the self in ways that closely match Erikson's description.

Paths to Identity

Using a clinical interviewing procedure devised by James Marcia (1980) or briefer questionnaire measures, researchers evaluate progress in identity development on two key criteria derived from Erikson's theory: *exploration* and *commitment.* Their various combinations yield four *identity statuses,* summarized in Table 11.1: **identity achievement,** commitment to values, beliefs, and goals following a period of exploration; **identity moratorium,** exploration without having reached commitment; **identity foreclosure,** commitment in the absence of exploration; and **identity diffusion,** an apathetic state characterized by lack of both exploration and commitment.

Identity development follows many paths. Some young people remain in one status, whereas others experience many status transitions. And the pattern often varies across *identity domains,* such as sexual orientation, vocation, and religious, political, and other worldviews. Many young people change from "lower" statuses (foreclosure or diffusion) to "higher" statuses (moratorium or achievement) between their mid-teens and mid-twenties, but about as many remain stable, and some move in the reverse direction (Kroger, 2005, 2007; Kroger, Martinussen, & Marcia, 2010). The number of domains explored and the intensity with which they are examined vary widely. Almost all young people grapple with work, close relationships, and family. Others add political, religious, community, and leisure-time commitments, some of which are more central to their identity than others.

TABLE 11.1 The Four Identity Statuses

IDENTITY STATUS	DESCRIPTION	EXAMPLE
Identity achievement	Having already explored alternatives, identity-achieved individuals are committed to a clearly formulated set of self-chosen values and goals. They feel a sense of psychological well-being, of sameness through time, and of knowing where they are going.	When asked how willing she would be to give up going into her chosen occupation if something better came along, Lauren responded, "Well, I might, but I doubt it. I've thought long and hard about law as a career. I'm pretty certain it's for me."
Identity moratorium	*Moratorium* means "delay or holding pattern." These individuals have not yet made definite commitments. They are in the process of exploring—gathering information and trying out activities, with the desire to find values and goals to guide their lives.	When asked whether he had ever had doubts about his religious beliefs, Ramón said, "Yes, I guess I'm going through that right now. I just don't see how there can be a God and yet so much evil in the world."
Identity foreclosure	Identity-foreclosed individuals have committed themselves to values and goals without exploring alternatives. They accept a ready-made identity chosen for them by authority figures—usually parents but sometimes teachers, religious leaders, or romantic partners.	When asked if she had ever reconsidered her political beliefs, Emily answered, "No, not really, our family is pretty much in agreement on these things."
Identity diffusion	Identity-diffused individuals lack clear direction. They are not committed to values and goals, nor are they actively trying to reach them. They may never have explored alternatives or may have found the task too threatening and overwhelming.	When asked about his attitude toward nontraditional gender roles, Justin responded, "Oh, I don't know. It doesn't make much difference to me. I can take it or leave it."

Because attending college provides opportunities to explore educational and career options as well as lifestyles, college students make more identity progress, increasingly engaging in focused, in-depth consideration and reconsideration of potential commitments (Klimstra et al., 2010; Luyckx et al., 2006; Montgomery & Côté, 2003). After college, young people often sample various life experiences through travel or short-term volunteer jobs in such programs as the U.S. Peace Corps. Those who go to work immediately after high school graduation often settle on a self-definition earlier. But if they encounter obstacles to realizing their occupational goals because of lack of training or vocational choices, they are at risk for long-term identity foreclosure or diffusion (Cohen et al., 2003; Eccles et al., 2003).

At one time, researchers thought that adolescent girls postponed establishing an identity, focusing instead on Erikson's next stage, intimacy development. Some girls do show more sophisticated reasoning in intimacy-related domains, such as sexuality and family versus career priorities. Otherwise, adolescents of both sexes typically make progress on identity concerns before experiencing genuine intimacy in relationships (Berman et al., 2006; Kroger, 2007).

© JIM WEST/THE IMAGE WORKS

Harvesting produce for a food bank provides these adolescents with an opportunity to explore community values and goals, potentially contributing to their identity development.

Identity Status and Psychological Well-Being

According to identity theorists, individuals who move away from foreclosure and diffusion toward moratorium and achievement build a well-structured identity that integrates various domains. As a result, they experience a gratifying sense of personal continuity, competence, and social connection—of being the same person across time and contexts and of becoming a capable, respected, member of the adult community (Luyckx et al., 2009; Snarey & Bell, 2003). A wealth of research supports the conclusion that identity achievement and moratorium are psychologically healthy routes to a mature self-definition, whereas long-term foreclosure and diffusion are maladaptive.

Although adolescents in moratorium are often anxious about the challenges they face, they resemble identity-achieved individuals in using an *active, information-gathering cognitive style* to make personal decisions and solve problems: They seek out relevant information, evaluate it carefully, and critically reflect on and revise their views (Berzonsky, 2003, 2011; Berzonsky & Kuk, 2000). Young people who are identity-achieved or exploring have higher self-esteem, are more open to alternative ideas and values, feel more in control of their own lives, are more likely to view school and work as feasible avenues for realizing their aspirations, and are more advanced in moral reasoning (Berzonsky et al., 2011; Kroger, 2007; Serafini & Adams, 2002). When asked for a "turning point" narrative (an account of a past event that they view as important in understanding themselves), identity-achieved individuals tell stories containing more sophisticated personal insights and portraying negative life events as followed by good outcomes—personal renewal, improvement, and enlightenment (McLean & Pratt, 2006).

Adolescents stuck in either foreclosure or diffusion are passive in the face of identity concerns and have adjustment difficulties. Foreclosed individuals display a *dogmatic, inflexible cognitive style,* internalizing the values and beliefs of parents and others without deliberate evaluation and resisting information that threatens their position (Berzonsky & Kuk, 2000; Berzonsky et al., 2011). Most fear rejection by people on whom they depend for affection and self-esteem. A few foreclosed teenagers who are alienated from their families and society may join cults or other extremist groups, uncritically adopting a way of life that is different from their past.

Long-term diffused teenagers are the least mature in identity development. They typically use a *diffuse-avoidant cognitive style* in which they avoid dealing with personal decisions and problems and, instead, allow current situational pressures to dictate their reactions (Berzonsky & Kuk, 2000; Krettenauer, 2005). Taking an "I don't care" attitude, they entrust themselves to luck or fate, tend to go along with the crowd, and are focused on short-term personal pleasure. As a result, they often experience time management and academic difficulties and, of

SOCIAL ISSUES: HEALTH

Adolescent Suicide: Annihilation of the Self

The suicide rate increases from childhood to old age, but it jumps sharply at adolescence. Currently, suicide is the third-leading cause of death among American youths, after motor vehicle collisions and homicides. Perhaps because U.S. teenagers experience more stresses and fewer supports than in the past, the adolescent suicide rate tripled between the mid-1960s and the mid-1990s, followed by a slight decline (Spirito & Esposito-Smythers, 2006; U.S. Census Bureau, 2011b). At the same time, rates of adolescent suicide vary widely among industrialized nations—low in Greece, Italy, the Netherlands, and Spain; intermediate in Australia, Canada, Japan, and the United States; and high in Finland, New Zealand, and Singapore (Bridge, Goldstein, & Brent, 2006). These international differences remain unexplained.

Factors Related to Adolescent Suicide

Striking sex differences in suicidal behavior exist. The number of boys who kill themselves exceeds the number of girls by a ratio of 3 or 4 to 1. Girls make more unsuccessful suicide attempts and use methods from which they are more likely to be revived, such as a sleeping pill overdose. In contrast, boys tend to choose techniques that lead to instant death, such as firearms or hanging (Langhinrichsen-Rohling, Friend, & Powell, 2009). Gender-role expectations may contribute; less tolerance exists for feelings of helplessness and failed efforts in males than in females.

Possibly due to higher levels of support from extended families, African Americans, Asian Americans, and Hispanics have lower suicide rates than Caucasian Americans. Recently, however, suicide has risen among African-American adolescent males; the current rate approaches that of Caucasian-American males. And Native-American youths commit suicide at rates two to six times national averages (Balis & Postolache, 2008; U.S. Census Bureau, 2011b). High rates of profound family poverty, school failure, alcohol and drug abuse, and depression probably underlie these trends.

Gay, lesbian, and bisexual youths also are at high risk, attempting suicide three times as often as other adolescents. Those who have tried to kill themselves report more family conflict over their gender-atypical behavior, inner turmoil about their sexuality, problems in romantic relationships, and peer rejection due to their sexual orientation (D'Augelli et al., 2005).

Suicide tends to occur in two types of young people. The first group includes adolescents who are highly intelligent but solitary, withdrawn, and unable to meet their own standards or those of important people in their lives. Members of a second, larger group show antisocial tendencies and express their despondency through bullying, fighting, stealing, increased risk taking, and drug abuse (Evans, Hawton, & Rodham, 2004). Besides being hostile and destructive, they turn their anger and disappointment inward.

Suicidal adolescents often have a family history of emotional and antisocial disorders and suicide. In addition, they are likely to have experienced multiple stressful life events, including economic disadvantage, parental separation and divorce, absence of family warmth, frequent parent–child conflict, and abuse and neglect. Stressors typically increase during the period preceding a suicide attempt or completion (Beautrais, 2003; Kaminski et al., 2010). Triggering events include parental blaming of the teenager for family problems, the breakup of an important peer relationship, or the humiliation of having been caught engaging in irresponsible, antisocial acts.

Public policies resulting in cultural disintegration have amplified suicide rates among Native-American youths. From the late 1800s to the 1960s or 1970s, Native families were forced to enroll their children in government-run residential boarding schools designed to erase tribal affiliations. In these repressive institutions, children were not allowed to "be

all young people, are the most likely to commit antisocial acts and to use and abuse drugs (Archer & Waterman, 1990; Berzonsky et al., 2011; Schwartz et al., 2005). Often at the heart of their apathy and impulsiveness is a sense of hopelessness about the future that puts many at risk for serious depression and suicide (see the Social Issues: Health box above).

Factors Affecting Identity Development

Adolescent identity formation begins a lifelong, dynamic process in which a change in either the individual or the context opens up the possibility of reformulating identity (Kunnen & Bosma, 2003). A wide variety of factors influence identity development.

Personality Identity status, as we have just seen, is both cause and consequence of personality characteristics. Adolescents who are conformist and obedient and who assume that absolute truth is always attainable tend to be foreclosed, whereas those who are self-indulgent and doubt they will ever feel certain about anything are more often identity-diffused. Young people who are curious and open-minded and who appreciate that they can use rational criteria to choose among alternatives are more likely to be in a state of moratorium or identity achievement (Berzonsky & Kuk, 2000; Berzonsky et al., 2011; Boyes & Chandler, 1992). This flexible, self-reflective approach helps them greatly in and pursuing educational, vocational, and other life goals.

Indian" in any way—culturally, linguistically, artistically, or spiritually (Goldston et al., 2008). The experience left many young people academically unprepared and emotionally scarred, contributing to family and community disorganization in current and succeeding generations. Consequently, alcohol abuse, youth crime, and suicide rates escalated (Barnes, Josefowitz, & Cole, 2006; Howell & Yuille, 2004). Today, perceived discrimination and weak identification with one's tribal culture remain powerful predictors of suicidal thoughts among Native-American youths (Yoder et al., 2006).

Why does suicide increase in adolescence? One factor seems to be teenagers' improved ability to plan ahead. Although some act impulsively, many young people at risk take purposeful steps toward killing themselves. Other cognitive changes also contribute. Belief in the personal fable (see Chapter 6) leads many depressed young people to conclude that no one could possibly understand their intense pain. As a result, despair, hopelessness, and isolation deepen.

Prevention and Treatment

Picking up on signals from a troubled teenager is a crucial first step in suicide prevention. Parents and teachers must be trained to recognize warning signs. Schools and community settings, such as recreational and religious organizations, can help by strengthening adolescents' connections with their cultural heritage and providing knowledgeable, approachable, and sympathetic adults, peer support groups, and information about telephone hot lines (Goldston et al., 2008; Spirito et al., 2003). Once a teenager takes steps toward suicide, staying with the young person, listening, and expressing compassion and concern until professional help can be obtained are essential.

Treatments for depressed and suicidal adolescents range from antidepressant medication to individual, family, and group therapy. Sometimes hospitalization is necessary to ensure the teenager's safety. Until the adolescent improves, removing weapons, knives, razors, scissors, and drugs from the home is vital. Strengthening social supports and training young people in effective strategies for coping with stress and depressed mood promote resilience and can prevent repeated suicide attempts (Asarnow et al., 2005; Kalafat, 2005). On a broader scale, gun-control legislation that limits adolescents' access to the most frequent and deadly suicide method in the United States would greatly reduce both the number of suicides and the high teenage homicide rate (Commission on Adolescent Suicide Prevention, 2005).

After a suicide, family and peer survivors need support to help them cope with grief, anger, and guilt over not having been able to help the victim. Teenage suicides often occur in clusters: One such death increases the likelihood of other suicides among depressed peers who knew the young person or heard about the death through the media (Bearman & Moody, 2004; Feigelman & Gorman, 2008). In view of this trend, an especially watchful eye must be kept on vulnerable adolescents after a suicide happens. Restraint by journalists in publicizing teenage suicides also aids prevention.

© SGO/BSIP/CORBIS

Individual, family, and group therapy can help adolescents develop effective strategies for coping with stress and depressed mood, promoting resilience and preventing repeated suicide attempts.

Family Teenagers' identity development is enhanced when their families serve as a "secure base" from which they can confidently move out into the wider world. In families of diverse ethnicities, adolescents who feel attached to their parents and say they provide effective guidance, but who also feel free to voice their own opinions, tend to be in a state of moratorium or identity achievement (Berzonsky, 2004; Luyckx et al., 2006; Schwartz et al., 2005). Foreclosed teenagers usually have close bonds with parents but lack opportunities for healthy separation. And diffused young people report the lowest levels of parental support and warm, open communication (Reis & Youniss, 2004; Zimmerman & Becker-Stoll, 2002).

Recall that parents who engage in positive problem solving—who resolve conflicts by seeking their child's input and collaborating on a solution—foster high self-esteem. Notice, also, how this approach promotes the balance between family relatedness and autonomy that supports identity development (Deci & Ryan, 2002).

Peers Interaction with diverse peers through school and community activities encourages adolescents to explore values and role possibilities (Barber et al., 2005). And close friends, like parents, can act as a secure base, providing emotional support, assistance, and models of identity development. In one study, 15-year-olds with warm, trusting peer ties were more involved in exploring relationship issues—for example, thinking about what they valued in a life partner (Meeus, Oosterwegel, & Vollebergh, 2002). In another study, college students' attachment to friends predicted progress in choosing a career (Felsman & Blustein, 1999).

APPLYING WHAT WE KNOW

Supporting Healthy Identity Development

STRATEGY	EXPLANATION
Engage in warm, open communication.	Provides both emotional support and freedom to explore values and goals.
Initiate discussions that promote high-level thinking at home and at school.	Encourages rational, deliberate selection among competing beliefs and values.
Provide opportunities to participate in extracurricular activities and vocational training programs.	Permits young people to explore the real world of adult work.
Provide opportunities to talk with adults and peers who have worked through identity questions.	Offers models of identity achievement and advice on how to resolve identity concerns.
Provide opportunities to explore ethnic heritage and learn about other cultures in an atmosphere of respect.	Fosters identity achievement in all areas and ethnic tolerance, which supports the identity explorations of others.

School, Community, and Culture Identity development also depends on schools and communities that offer rich and varied opportunities for exploration. Supportive experiences include classrooms that promote high-level thinking, teachers and counselors who encourage low-SES and ethnic minority students to go to college, extracurricular and community activities that offer teenagers responsible roles consistent with their interests and talents, and vocational training that immerses adolescents in the real world of adult work (Coatsworth et al., 2005; Cooper, 1998).

Culture strongly influences an aspect of mature identity not captured by the identity-status approach: constructing a sense of self-continuity despite major personal changes. In one study, researchers asked Native Canadian and cultural-majority 12- to 20-year-olds to describe themselves in the past and in the present and then to justify why they were the same continuous person (Lalonde & Chandler, 2005). Both groups gave increasingly complex responses with age, but their strategies differed. Most cultural-majority adolescents used an individualistic approach: They described an *enduring personal essence,* a core self that remained the same despite change. In contrast, Native Canadian youths took an interdependent approach that emphasized a *constantly transforming self,* resulting from new roles and relationships. They typically constructed a *coherent narrative* in which they linked together various time slices of their life with a thread explaining how they had changed in meaningful ways.

Finally, societal forces are also responsible for the special challenges faced by gay, lesbian, and bisexual youths (see Chapter 5) and by ethnic minority adolescents in forming a secure identity (see the Cultural Influences box on the following page). Applying What We Know above summarizes ways that adults can support adolescents in their quest for identity.

ASK YOURSELF

Review ■ List personal and contextual factors that promote identity development.

Connect ■ Explain the close link between adolescent identity development and cognitive processes.

Apply ■ Eighteen-year-old Brad's parents worry that he will waste time at college because he is unsure about his major and career goals. Explain why Brad's uncertainty might be advantageous for his identity development.

Reflect ■ Does your identity status vary across the domains of sexuality, close relationships, vocation, religious beliefs, and political values? Describe factors that may have influenced your identity development in an important domain.

CULTURAL INFLUENCES

Identity Development Among Ethnic Minority Adolescents

Most adolescents are aware of their cultural ancestry but relatively unconcerned about it. However, for teenagers who are members of minority groups, **ethnic identity**—a sense of ethnic group membership and attitudes and feelings associated with that membership—is central to the quest for identity. As they develop cognitively and become more sensitive to feedback from the social environment, minority youths become painfully aware that they are targets of prejudice and discrimination. This discovery complicates their efforts to develop a sense of cultural belonging and a set of personally meaningful goals.

Minority youths often feel caught between the standards of the larger society and the traditions of their culture of origin. In many immigrant families from collectivist cultures, adolescents' commitment to obeying their parents and fulfilling family obligations lessens the longer the family has been in the immigrant-receiving country—a circumstance that induces **acculturative stress,** psychological distress resulting from conflict between the minority and the host culture (Phinney, Ong, & Madden, 2000). When immigrant parents tightly restrict their teenagers through fear that assimilation into the larger society will undermine their cultural traditions, their youngsters often rebel, rejecting aspects of their ethnic background.

At the same time, discrimination can interfere with the formation of a positive ethnic identity. In one study, Mexican-American youths who had experienced more discrimination were less likely to explore their ethnicity and to report feeling good about it (Romero & Roberts, 2003). Those with low ethnic pride showed a sharp drop in self-esteem in the face of discrimination.

With age, some ethnic minority young people progress from ethnic-identity diffusion or foreclosure through moratorium to ethnic-identity achievement. But because the process of forging an ethnic identity can be painful and confusing, others show no change, and still others regress (Seaton, Scottham, & Sellers, 2006). Young people with parents of different ethnicities face extra challenges. In a large survey of high school students, part-black biracial teenagers reported as much discrimination as their monoracial black counterparts, yet they felt less positively about their ethnicity. And compared with monoracial minorities, many biracials—including black–white, black–Asian, white–Asian, black–Hispanic, and white–Hispanic—regarded ethnicity as less central to their identities (Herman, 2004). Perhaps these adolescents encountered fewer opportunities in their homes and communities to forge a strong sense of belonging to either culture.

Adolescents whose family members encourage them to disprove ethnic stereotypes of low achievement or antisocial behavior typically surmount the threat that discrimination poses to a favorable ethnic identity. These young people manage experiences of unfair treatment effectively, by seeking social support and engaging in direct problem solving (Phinney & Chavira, 1995; Scott, 2003). Also, adolescents whose families taught them the history, traditions, values, and language of their ethnic group and who frequently interact with same-ethnicity peers are more likely to forge a favorable ethnic identity (Hughes et al., 2006; McHale et al., 2006).

© DAVID M. GROSSMAN/THE IMAGE WORKS

Stilt walkers celebrate their heritage at a Caribbean youth festival. Minority youths whose cultural heritage is respected in their communities are more likely to incorporate ethnic values and customs into their identity.

How can society help minority adolescents resolve identity conflicts constructively? Here are some relevant approaches:

- Promote effective parenting, in which children and adolescents benefit from family ethnic pride yet are encouraged to explore the meaning of ethnicity in their own lives.
- Ensure that schools respect minority youths' native languages, unique learning styles, and right to a high-quality education.
- Foster contact with peers of the same ethnicity, along with respect between ethnic groups (García Coll & Magnuson, 1997).

A strong, secure ethnic identity is associated with higher self-esteem, optimism, a sense of mastery over the environment, and more positive attitudes toward one's ethnicity (St. Louis & Liem, 2005; Umaña-Taylor & Updegraff, 2007; Worrell & Gardner-Kitt, 2006). For these reasons, adolescents with a positive connection to their ethnic group are better-adjusted. They cope more effectively with stress, report higher levels of psychological well-being, show better achievement in school, and have fewer emotional and behavior problems than agemates who identify only weakly with their ethnicity (Ghavami et al., 2011; Greene, Way, & Pahl, 2006; Seaton, Scottham, & Sellers, 2006; Umaña-Taylor & Alfaro, 2006). For teenagers faced with potential or actual adversity, ethnic identity is a powerful source of resilience.

Forming a **bicultural identity**—by exploring and adopting values from both the adolescent's subculture and the dominant culture—offers added benefits. Biculturally identified adolescents tend to be achieved in other areas of identity as well and to have especially favorable relations with members of other ethnic groups (Phinney, 2007; Phinney et al., 2001). In sum, achievement of ethnic identity enhances many aspects of emotional and social development.

- Discuss changes in children's appreciation of others' attributes and understanding of social groups, including factors that contribute to prejudice and ways to reduce it.

Thinking About Other People

Children's understanding of other people—the inferences they make about their attributes, both as individuals and as members of particular social groups—has much in common with their developing understanding of themselves. As we will see, these facets of social cognition also become increasingly differentiated and well organized with age.

Understanding People as Personalities

Person perception refers to the way we size up the qualities of people with whom we are familiar. Researchers study person perception by asking children to describe people they know, using methods similar to those that focus on children's self-concepts. For example, the researcher might ask, "Can you tell me what kind of person ____ is?"

Like their self-descriptions, young children's descriptions of others focus on concrete activities, behaviors, and commonly experienced emotions and attitudes. As noted in our discussion of self-concept, older preschoolers have begun to notice consistencies in the actions and internal states of people they know (see page 456). Around age 8, they mention personality traits. At first, these references are closely tied to behavior and consist of implied dispositions: "He's always fighting with people" or "She steals and lies" (Rholes, Newman, & Ruble, 1990). Later, children mention traits directly, but they use vague, stereotyped language, such as "good," "nice," or "acts smart." Gradually, sharper trait descriptions appear—"honest," "trustworthy," "generous," "polite," "selfish"—and children become more convinced of the stability of such dispositions (Droege & Stipek, 1993; Ruble & Dweck, 1995).

During adolescence, as abstract thinking becomes better established, inferences about others' personalities are drawn together into organized character sketches (O'Mahoney, 1989). As a result, between ages 14 and 16, teenagers present rich accounts of people they know that integrate physical traits, typical behaviors, and inner dispositions.

Understanding Social Groups: Race and Ethnicity

Children's person perception, like that of adults, is strongly influenced by social-group membership. As we will see, at an early age, children begin to acquire stereotypes about social groups, and those stereotypes can easily overwhelm their capacity to size up people as individuals.

As with their categorical self (see page 450), young children classify people into social groups on the basis of perceptually distinct attributes, such as age, gender, and race. Children's understanding of gender has been so extensively investigated that we will address it in detail in Chapter 13. Here we focus on a rapidly growing literature on children's developing conceptions of race and ethnicity.

Most 3- and 4-year-olds have formed basic concepts of race and ethnicity, in that they can apply the labels "black" and "white" to pictures, dolls, and people (Aboud, 2003). Although indicators of social class—education and occupational prestige—are not accessible to young children, they can distinguish rich from poor on the basis of physical characteristics, such as clothing, residence, and possessions (Ramsey, 1991).

By the early school years, children absorb prevailing societal attitudes, associating power and privilege with white people and poverty and inferior status with people of color. They do not necessarily acquire these views directly from parents or friends. In one study, although white school-age children assumed that parents' and friends' racial attitudes would resemble their own, no similarities in attitudes emerged (Aboud & Doyle, 1996). Perhaps white parents are reluctant to discuss their racial and ethnic views with children, and friends also say little. Given limited or ambiguous information, children seem to fill in the gaps with information they encounter in their environments and then infer others' attitudes on the basis of their own.

Consistent with this idea, research indicates that children pick up much information about group status from messages in their surroundings. These include (1) social contexts that present a world sorted into groups, such as racial and ethnic segregation in schools and communities; and (2) experiences involving explicit labeling of groups, even when the group distinctions presented are neutral rather than stereotypic (Bigler & Liben, 2007).

In one experiment, 7- to 12-year-olds attending a summer school program were randomly assigned to social groups, denoted by colored T-shirts (yellow or blue) that the children wore. The researchers hung posters in the classroom that depicted unfamiliar yellow-group members as having higher status—for example, as having won more athletic and spelling competitions. When teachers recognized the social groups by using them as the basis for seating arrangements, task assignments, and bulletin-board displays, children in the high-status group evaluated their own group more favorably than the other group, and children in the low-status group viewed their own group less favorably (Bigler, Brown, & Markell, 2001). But when teachers ignored the social groupings, no prejudice emerged.

These findings indicate that children do not necessarily form stereotypes even when some basis for them exists—in this instance, information on wall posters. But when an authority figure validates a status hierarchy by labeling, sorting, or treating groups differently, children do form biased attitudes.

In-Group and Out-Group Biases: Development of Prejudice Studies in diverse Western nations confirm that by age 5 to 6, white children generally evaluate their own racial group favorably and other racial groups less favorably or negatively—biases that also characterize many adults. *In-group favoritism* emerges first; children simply prefer their own group, generalizing from self to similar others (Bennett et al., 2004; Cameron et al., 2001). And the ease with which a trivial group label supplied by an adult can induce in-group favoritism is striking. In one study, Caucasian-American 5-year-olds were told that they were members of a group based on T-shirt color, but this time, no information was provided about group status, and the children never met any group members. Still they displayed vigorous in-group favoritism (Dunham, Baron, & Carey, 2011). When shown photos of unfamiliar agemates wearing either an in-group or an out-group shirt, the children claimed to like members of their own group better, gave them more resources, expected more generous behavior from them, and engaged in biased recall of individuals' behavior that favored the in-group.

Out-group prejudice requires a more challenging social comparison between in-group and out-group. But it does not take long for white children to acquire negative attitudes toward ethnic minority out-groups, especially when such attitudes are encouraged by circumstances in their environments. When white Canadian 4- to 7-year-olds living in a white community and attending nearly all-white schools sorted positive and negative adjectives into boxes labeled as belonging to a white child and a black child, out-group prejudice emerged at age 5 (see Figure 11.8) (Aboud, 2003).

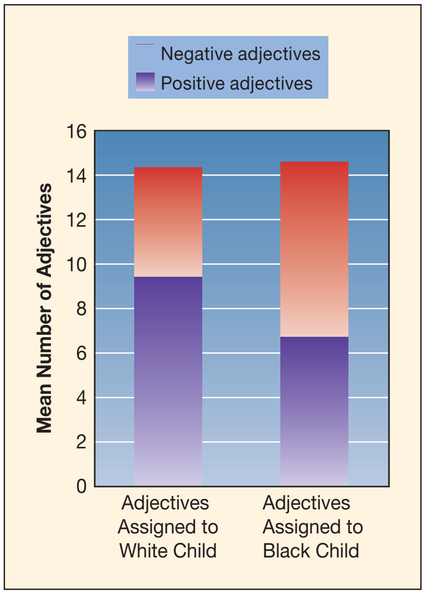

FIGURE 11.8 **White Canadian 5-year-olds' expressions of in-group favoritism and out-group prejudice.** When asked to sort positive and negative adjectives into boxes labeled as belonging to a white child and a black child, white Canadian 5-year-olds assigned a greater number of positive adjectives (such as *clean, nice, smart*) to the white child than to the black child—evidence for in-group favoritism. In addition to viewing the black child less positively, the white Canadian 5-year-olds also assigned a greater number of negative adjectives (such as *dirty, naughty, cruel*) to the black child—evidence for *out-group prejudice.* (Adapted from Aboud, 2003.)

Unfortunately, many ethnic minority children show a reverse pattern: *out-group favoritism,* in which they assign positive characteristics to the privileged ethnic majority and negative characteristics to their own group. In one study, researchers asked African-American 5- to 7-year-olds to recall information in stories either consistent or inconsistent with stereotypes of blacks. The children recalled more stereotypic traits, especially if they agreed with negative cultural views of African Americans or rated their own skin tone as lighter and, therefore, may have identified themselves with the white majority (Averhart & Bigler, 1997). In a similar investigation, Native Canadian second to fourth graders recalled more positive attributes about white Canadians and more negative attributes about Native Canadians (Corenblum, 2003). A societal context that devalues people of color makes minority children vulnerable to internalizing those beliefs.

But recall that with age, children pay more attention to inner traits. The capacity to classify the social world in multiple ways enables school-age children to understand that people can be both "the same" and "different"—those who look different need not think, feel, or act differently (Aboud, 2008). Consequently, voicing of negative attitudes toward minorities declines. After age 7 to 8, both majority and minority children express *in-group favoritism,* and white children's prejudice against *out-group* members often weakens (Nesdale et al., 2005; Ruble et al., 2004). Most school-age children and adolescents are also quick to verbalize that it is wrong to exclude others from peer-group and learning activities on the basis of skin color—discrimination they evaluate as unfair (Killen et al., 2002).

Yet even in children and adolescents who are aware of the injustice of discrimination, prejudice can operate subtly, unintentionally, and without awareness—as it does in many white adults (Dovidio et al., 2004; Dunham, Baron, & Banaji, 2006). Consider a study in which white second and fourth graders were asked to divide fairly among three child artists—two white and one black—money that had been earned from selling the children's art. In each version of the task, one artist was labeled as "productive" (making more art works), one as "the oldest," and one as "poor and needing money for lunch." By age 8 to 9, most children recognize that special consideration is appropriate for children who perform exceptionally or are at a disadvantage. But racial stereotypes interfered with fourth graders' even-handed application of these principles. They gave more money to a productive black artist (who countered the racial stereotype of "low achiever") than to a productive white artist and less money to a needy black artist (who conformed to the racial stereotype of "poor") than to a needy white artist (see Figure 11.9) (McGillicuddy-De Lisi, Daly, & Neal, 2006).

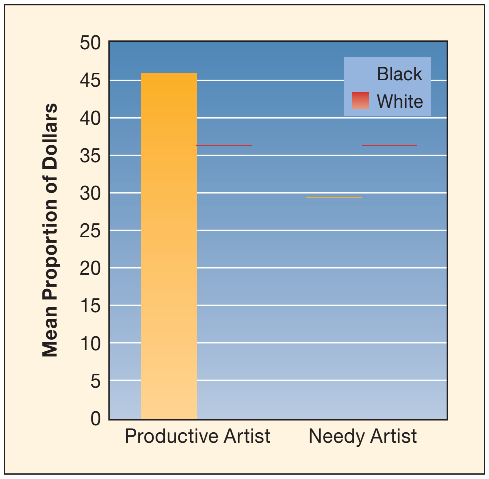

FIGURE 11.9 White fourth graders' racially biased distribution of money to child artists. When dividing money earned from selling children's art among three child artists—two white and one black—the fourth graders gave more money to a productive black artist (who countered a stereotype) than to a productive white artist and less money to a needy black artist (who conformed to a stereotype) than to a needy white artist. In both instances, the fourth graders seemed to engage in subtle, unintentional prejudice. (From A. V. McGillicuddy-De Lisi, M. Daly, & A. Neal, 2006, "Children's Distributive Justice Judgments: Aversive Racism in Euro-American Children?" *Child Development, 77,* p. 1072. Copyright © 2006, John Wiley and Sons. Adapted by permission of John Wiley and Sons.)

Findings like these raise the question of whether the decline in overt racial bias during middle childhood is a true decrease or whether it reflects older children's growing awareness of widely held standards that deem prejudice to be inappropriate—or (more likely) both. Around age 10, most children have internalized social norms and become increasingly concerned that their attitudes and behaviors are seen as consistent with them (Selman, 1980). Simultaneously, white children start to avoid talking about race to appear unbiased, just as many adults do. In a matching game in which willingness to label photos of people by race aided performance, 10- and 11-year-olds were so reluctant to mention race that they performed more poorly than 8- and 9-year-olds, who freely used racial descriptors (Apfelbaum et al., 2008). At least to some degree, then, older school-age children's desire to present themselves in a socially acceptable light may contribute to reduced expressions of out-group prejudice.

Nevertheless, the extent to which children hold racial and ethnic biases varies, depending on the following personal and situational factors:

- *A fixed view of personality traits.* Children who believe that people's personality traits are fixed rather than changeable often judge others as either "good" or "bad." Ignoring motives and circumstances, they readily form extreme impressions on the basis of limited information. For example, they might infer that "a new child at school who tells a lie to try to get other kids to like her" is a simply bad kid (Heyman & Dweck, 1998; Levy & Dweck, 1999).
- *Overly high self-esteem.* Children (and adults) with very high self-esteem are more likely to hold racial and ethnic prejudices (Baumeister et al., 2003; Bigler, Brown, & Markell, 2001). These narcissistic individuals seem to belittle disadvantaged individuals or groups to justify and protect their own extremely favorable, yet insecure, self-evaluations. Furthermore, children of diverse backgrounds who say their own ethnicity makes them feel especially "good"—and thus perhaps socially superior—are more likely to display in-group favoritism and out-group prejudice (Pfeifer et al., 2007).
- *A social world in which people are sorted into groups.* The more adults highlight group distinctions and the less interracial contact that is available in families, schools, and communities, the more likely white children and adolescents will express in-group favoritism and out-group prejudice (Killen et al., 2010). For example, white children with little other-group contact are highly vulnerable to expressions of subtle prejudice, such as interpreting an African-American agemate in an ambiguous situation as engaged in bad behavior (cheating, stealing, or otherwise harming others) (McGlothlin & Killen, 2006).

Reducing Prejudice Research confirms that an effective way to reduce prejudice—in children and adults alike—is through intergroup contact, in which racially and ethnically different individuals have equal status, work toward common goals, and become personally acquainted, and in which authority figures (such as parents and teachers) expect them to engage in such interaction. Children assigned to cooperative learning groups with peers of diverse backgrounds show low levels of prejudice in their expressions of likability and in their behavior. For example, they form more cross-race friendships (Pettigrew & Tropp, 2006). Sharing of thoughts and feelings with close cross-race friends, in turn, reduces even subtle, unintentional prejudices, which are highly resistant to change (Turner, Hewstone, & Voci, 2007). But the positive effects of cooperative learning seem not to generalize to out-group members who are not part of these learning teams.

Long-term contact and collaboration among neighborhood, school, and community groups may be the best way to reduce prejudice (Rutland, Killen, & Abrams, 2010). Consistent with this view, white 5- and 6-year-olds attending an ethnically mixed school relied on their everyday experiences to construct generally positive out-group attitudes (Aboud, 2003). Classrooms that expose children to broad ethnic diversity, teach them to understand and value those differences, directly address the damage caused by prejudice and discrimination, emphasize moral values of justice and fairness, and encourage perspective taking and empathy both prevent children from forming negative biases and reduce already acquired biases (Pfeifer, Brown, & Juvonen, 2007).

In addition, inducing children to view others' traits as malleable is helpful. The more school-age children and adolescents believe that people can change their personalities, the more they report liking, wanting to spend time with, and perceiving themselves as similar to members of disadvantaged out-groups. Furthermore, young people who believe in the malleability of human attributes spend more time volunteering to help the needy—for example, by serving meals to the homeless or reading to poverty-stricken preschoolers (Karafantis & Levy, 2004). Volunteering may, in turn, promote a malleable view of others by inducing young people to imagine themselves in the place of the underprivileged and thus helping them appreciate the social conditions that lead to disadvantage.

© MICHAEL J. DOOLITTLE/THE IMAGE WORKS

Fourth graders prepare to perform a Hindu dance for International Day at their culturally diverse school. Long-term contact and collaboration with members of other ethnic groups reduce prejudice.

Regrettably, despite the 1954 U.S. Supreme Court *Brown v. Board of Education* decision ordering schools to desegregate, school integration in the United States—which increased steadily until the late 1980s—has receded dramatically as courts terminated their desegregation orders and returned this authority to states and cities. Most U.S. white, black, and Hispanic students now attend schools where the majority of their fellow students are of their own race. White students are the most isolated group—typically in schools that are 80 percent white. And when African-American and Hispanic students attend mixed-race schools, they usually do so with other minorities (Frankenberg, Lee, & Orfield, 2003). Consequently, today's U.S. schools seldom offer exposure to the diversity necessary for countering negative racial and ethnic biases but, instead, largely perpetuate prejudices. Ideals and policies promoting interethnic contact and respect yield far more extensive school integration in Canada. Still, in both nations, 30 to 40 percent of Native children (Native American and Native Canadian) live on reservation lands, where they attend segregated schools (Statistics Canada, 2008; U.S. Census Bureau, 2011b).

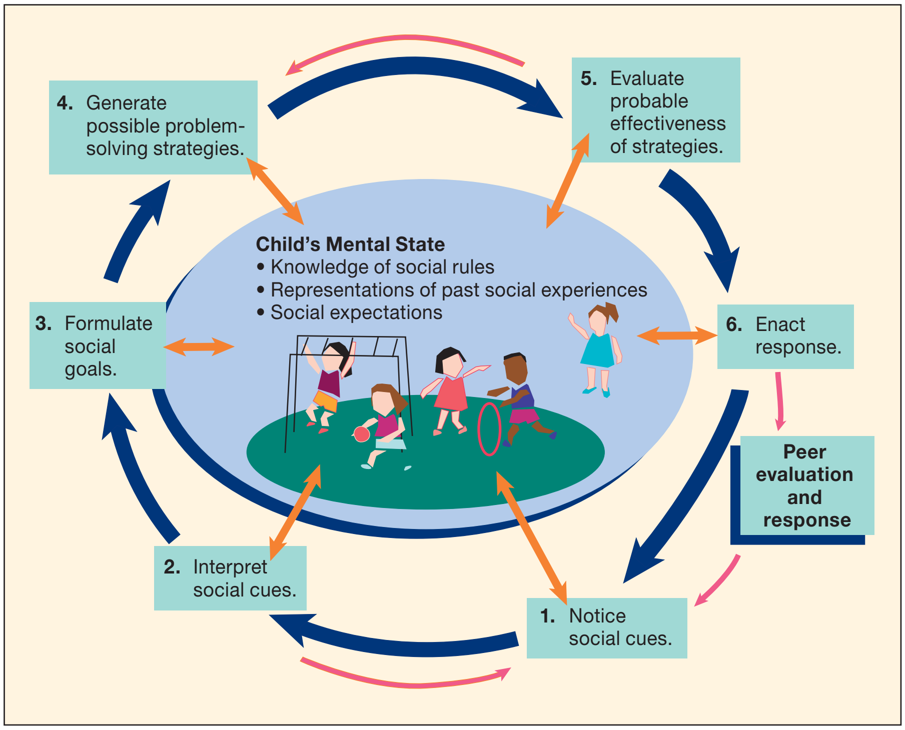
Many studies indicate that attending integrated classrooms leads to higher achievement, educational attainment, and occupational aspirations among ethnic minority students—especially when integration begins in the early grades (Hanushek, Kain, & Rivkin, 2002). School integration also greatly increases the likelihood that young people will lead integrated lives as adults (Schofield, 1995). Environments in which students of diverse ethnicities learn together offer a common, inclusive social identity that reduces intergroup bias (Cameron et al., 2006; Dweck, 2009). Furthermore, integrated schools provide many opportunities to grapple with multiple perspectives, which challenge students to think about their social world in more complex ways. As we saw earlier in this chapter, school-age children's developing capacity to take the perspective of others—especially, their ability to engage in recursive thought—contributes greatly to interpersonal understanding and positive social behavior.

- Discuss the development of social problem-solving skills, noting ways to enhance social problem solving in children.

Understanding Conflict: Social Problem Solving

Children, including those who are good friends, sometimes come into conflict. With age, they apply their insights about themselves and others to an understanding of how to resolve situations in which their goals and the goals of agemates are at odds. Even preschoolers seem to handle most quarrels constructively; only rarely do their disagreements result in hostile encounters. Overall, conflicts are not very frequent when compared with children's friendly, cooperative interactions.

TAKE A MOMENT... At your next opportunity, observe young children's play, noting their disputes over objects ("That's mine!" "I had it first!"), entry into and control over play activities ("I'm on your team, Jerry." "No, you're not!"), and disagreements over facts, ideas, and beliefs ("I'm taller than he is." "No, you aren't!"). Children take these matters quite seriously. From the preschool to the school years, conflicts shift from material concerns to psychological and social issues (Chen et al., 2001). In Chapter 6, we noted that resolution of conflict, rather than conflict per se, promotes development. Social conflicts provide repeated occasions for **social problem solving**—generating and applying strategies that prevent or resolve disagreements, resulting in outcomes that are both acceptable to others and beneficial to the self. To engage in social problem solving, children must bring together diverse social understandings.



4. Generate possible problem-solving strategies.
5. Evaluate probable effectiveness of strategies.
Child's Mental State
• Knowledge of social rules
• Representations of past social experiences
• Social expectations
3. Formulate social goals.
6. Enact response.
Peer evaluation and response
2. Interpret social cues.
1. Notice social cues.

FIGURE 11.10 **An information-processing model of social problem solving.** The model is circular because children often engage in several information-processing activities at once—for example, interpreting information as they notice it and continuing to consider the meaning of another's behavior while they generate and evaluate problem-solving strategies. The model also takes into account the impact of mental state on social information processing—in particular, children's knowledge of social rules, their representations of past social experiences, and their expectations for future experiences. Peer evaluations and responses to enacted strategies are also important factors in social problem solving. (Adapted from N. R. Crick and K. A. Dodge, 1994, "A Review and Reformulation of Social Information-Processing Mechanisms in Children's Social Adjustment," *Psychological Bulletin, 115,* 74–101, Figure 2 [adapted], pg. 76. Copyright © 1994 by the American Psychological Association. Reprinted with permission of the American Psychological Association.)

The Social Problem-Solving Process

Nicki Crick and Kenneth Dodge (1994) organize the steps of social problem solving into the circular model shown in Figure 11.10. Notice how this flowchart takes an *information-processing approach,* clarifying exactly what a child must do to grapple with and solve a social problem. It enables identification of processing deficits, so intervention can be tailored to meet individual needs.

Social problem solving profoundly affects peer relations. Children who get along well with agemates interpret social cues accurately, formulate goals (being helpful to peers) that enhance relationships, and have a repertoire of effective problem-solving strategies—for example, politely asking to play and requesting an explanation when they do not understand a peer's behavior. In contrast, children with peer difficulties often hold biased social expectations. Consequently, they attend selectively to social cues (such as hostile acts) and misinterpret others' behavior (view an unintentional jostle as hostile). Their social goals (satisfying an impulse, getting even with or avoiding a peer) often lead to strategies that damage relationships (Dodge, Coie, & Lynam, 2006; Youngstrom et al., 2000). They might barge into a play group without asking, use threats and physical force, or fearfully hover around peers' activities.

Children improve greatly in social problem solving over the preschool and early school years, largely as a result of gains in perspective-taking capacity—in particular, recursive thought (Carpendale & Lewis, 2006). Instead of grabbing, hitting, or insisting that another child obey, 5- to 7-year-olds tend to rely on friendly persuasion and compromise, to think of alternative strategies when an initial one does not work, and to resolve disagreements without adult intervention (Chen et al., 2001; Mayeux & Cillessen, 2003). Sometimes they suggest creating new, mutual goals, reflecting awareness that how they solve current problems will influence the future of the relationship (Yeates, Schultz, & Selman, 1991). By kindergarten, the accuracy and effectiveness of each component of social problem solving are related to socially competent behavior (Dodge et al., 1986).

LOOK and LISTEN

At a playground, beach, or other public setting, watch for an hour or so as young children play, noting how they resolve conflicts. Do nearby adults guide them in social problem solving? How effective are adult interventions?

Enhancing Social Problem Solving

Intervening with children who have weak social problem-solving skills can enhance development in several ways. Besides improving peer relations, effective social problem solving gives children a sense of mastery in the face of stressful life events. It reduces the risk of adjustment difficulties in children from low-SES and troubled families (Goodman, Gravitt, & Kaslow, 1995).

In one intervention—the *Promoting Alternative Thinking Strategies (PATHS)* curriculum for preschool children—teachers provide children with weekly lessons in the ingredients of social problem solving. Using stories, puppet characters, discussion, and role-play demonstrations, they teach such skills as detecting others' thoughts and feelings, planning sequences of action, generating effective strategies, and anticipating probable outcomes. In evaluations of PATHS, preschoolers who had completed 30 lessons in their Head Start classrooms scored higher than no-intervention controls in accurately "reading" others' thoughts and emotions, selecting competent solutions to social conflicts, and cooperating and communicating verbally with peers (Bierman et al., 2008; Domitrovich, Cortes, & Greenberg, 2007).

Generating and evaluating strategies, however, are only part of the social problem-solving process. In a comprehensive year-long intervention called *Making Choices,* third graders diverse in SES received multiple lessons on each social problem-solving component depicted in Figure 11.10 as a supplement to their routine health curriculum. And those in a Making Choices–Plus condition received the intervention plus teacher and family enhancements: Teachers were given guidance in positive classroom discipline and in implementing activities aimed at strengthening emotion regulation, and parents received newsletters offering suggestions for follow-up exercises at home (Fraser et al., 2005, 2011). Regardless of SES, intervention children—compared with children in regular health classes—gained in teacher-rated social competence and declined in aggression over the school year, with reduced aggression still evident at a six-month follow up. Children in the Making Choices–Plus condition performed especially well on story-based assessments of knowledge of the various social problem-solving steps.

© CINDY CHARLES/PHOTOEDIT

In role-playing a conflict, these elementary school students learn to resolve social problems by considering others' perspectives and also practice effective solution strategies.

Practice in enacting responses may strengthen intervention outcomes. Sometimes children know how to solve a social problem effectively but do not apply their knowledge (Rudolph & Heller, 1997). And children who have repeatedly enacted maladaptive responses may need to rehearse alternatives to overcome their habitual behaviors and to spark more adaptive social information processing.

On a final note, programs aimed at augmenting perspective taking and social problem solving are not the only approaches to helping children with social difficulties. Because their parents often model poor social skills and use ineffective child-rearing practices, intensive family intervention may be necessary—a topic we will return to several times in later chapters.

ASK YOURSELF

Review ■ Explain how improved perspective taking contributes to gains in social problem solving from early to middle childhood.

Connect ■ How might school integration contribute to social–cognitive capacities that reduce prejudice, including perspective taking and empathy?

Apply ■ Ten-year-old Marla believes her classmate Becky will never get good grades because she's lazy. Jane believes that Becky tries but can't concentrate because her parents are divorcing. Why is Marla more likely than Jane to develop prejudices?

Reflect ■ Describe several efforts by schools, religious institutions, and youth organizations in your community to combat racial and ethnic prejudices in children.

SUMMARY

Emergence of Self and Development of Self-Concept (p. 448)

Describe the development of self-awareness in infancy and toddlerhood, along with the emotional and social capacities it supports.

- Self-awareness begins at birth, supported by newborns' capacity for intermodal perception. Three- to 4-month-olds' reactions to their own visual image suggest an implicit awareness of being physically distinct from their surroundings.
- Around age 2, **self-recognition** is well under way. Toddlers become explicitly aware of the self's physical features, as indicated by responses to their own image in mirrors and photos and use of personal pronouns. However, toddlers lack an objective understanding of their own body size, as indicated by their **scale errors**.
- Sensitive caregiving promotes early self-development. Toddlers in collectivist cultures with a proximal parenting style attain self-recognition later.
- Increasing self-awareness sets the stage for social referencing, self-conscious emotions, perspective taking, empathy, sustained imitative play, peer competition for objects, and cooperation.

Describe the development of the categorical, remembered, and enduring selves.

- Language development permits young preschoolers to construct a **categorical self** as they classify themselves and others on the basis of age, perceptually distinct attributes and behaviors, and goodness and badness. Adult–child conversations about the past lead to an autobiographical memory that grants the child a **remembered self** and an **enduring self.**

Discuss theory-of-mind development from early to middle childhood, citing social consequences and contributing factors.

- Young preschoolers develop an **inner self** of private thoughts and imaginings, which contributes vitally to **perspective taking.** As toddlers and young preschoolers comprehend mental states that can be readily inferred from their own and others' actions, they form a **desire theory of mind,** thinking that people's actions are always consistent with their desires.
- Between ages 3 and 4, children develop a **belief–desire theory of mind,** as mastery of false belief reveals. As school-age children realize that people can increase their knowledge by making mental inferences, they grasp second-order false belief. Performance on other complex tasks requiring **recursive thought** also improves over middle childhood.

© LAURA DWIGHT PHOTOGRAPHY

- False-belief understanding is associated with gains in sociodramatic play, with early reading ability, with more accurate eyewitness memory, and with social skills. School-age children use their capacity for recursive thought to clear up misunderstandings and to persuade others.
- Factors contributing to the development of theory of mind include language and verbal reasoning; executive function; parent–child conversations about mental states; make-believe play; and social interaction with siblings, friends, and adults.

Discuss the development of self-concept from early childhood through adolescence, noting cognitive, social, and cultural influences.

- As children think more intently about themselves, they construct a **self-concept.** In middle childhood, self-concept shifts from a focus on observable characteristics and typical emotions and attitudes to competencies, personality traits, and **social comparisons.** Adolescents unify separate traits into more abstract descriptors, forming an organized system that emphasizes social virtues and personal and moral values.
- Changes in self-concept are supported by cognitive development, perspective-taking skills (as suggested by Mead's concept of the **generalized other**), and feedback from others. Self-concept varies across cultures: Children in individualistic cultures focus on personal characteristics, those in collectivist cultures on group membership and relationships.

Self-Esteem: The Evaluative Side of Self-Concept (p. 461)

Discuss development of and influences on self-esteem from early childhood through adolescence.

- **Self-esteem** becomes hierarchically organized and declines over the first few years of elementary school as children start to make social comparisons. Except for a temporary drop associated with school transition, self-esteem rises from fourth grade on, with new dimensions added in adolescence.
- From middle childhood to adolescence, individual differences in self-esteem become increasingly stable. Favorable self-esteem profiles are associated with positive adjustment; low self-esteem in all areas is linked to adjustment difficulties. Cultural forces, including relative emphasis on social comparison and gender-stereotyped expectations, affect self-esteem.

- Children whose parents are warm and accepting and who provide reasonable expectations for mature behavior have higher self-esteem. Excessive parental control is linked to low self-esteem and indulgent parenting to unrealistically high self-esteem.

© MICHAEL NEWMAN/PHOTOEDIT

Discuss achievement-related attributions, and suggest ways to foster a mastery-oriented approach in children.

- School-age children begin to distinguish ability, effort, and external factors in their **attributions** for success and failure. Children with **mastery-oriented attributions** credit their successes to high ability and their failures to insufficient effort and hold an **incremental view of ability.** Children with **learned helplessness** attribute successes to external factors, such as luck, and failures to low ability and hold an **entity view of ability.**

© ALEX MARES-MANTON/ GETTY IMAGES/ASIA IMAGES

- Children who experience negative feedback about their ability, messages that evaluate their traits, and pressure to focus on performance goals are likely to develop learned helplessness. Caring, helpful parents and teachers who emphasize learning goals foster a mastery orientation. **Attribution retraining** encourages learned-helpless children to believe they can overcome failure through effort.

Constructing an Identity: Who Should I Become?

(p. 468)

Describe the four identity statuses, along with factors affecting identity development.

- Erikson first recognized formation of an **identity** as the major personality achievement of adolescence. **Identity achievement** (exploration followed by commitment) and **identity moratorium** (exploration without having reached commitment) are psychologically healthy identity statuses. Long-term **identity foreclosure** (commitment without exploration) and **identity diffusion** (lack of both exploration and commitment) are related to adjustment difficulties.
- An information-gathering cognitive style, parental attachment along with freedom to explore, interaction with diverse peers, close friendships, and schools and communities that provide rich and varied opportunities promote healthy identity development. Similarly, supportive parents, peers, and schools can foster a secure **ethnic identity** among minority adolescents. A **bicultural identity** offers additional emotional and social benefits.

Thinking About Other People **(p. 476)**

Discuss changes in children's appreciation of others' attributes and understanding of social groups, including factors that contribute to prejudice and ways to reduce it.

- **Person perception** refers to how we size up the qualities of familiar people. Like their self-descriptions, children's descriptions of others increasingly emphasize personality traits and become more organized with age.
- Basic concepts of race, ethnicity, and social class emerge in the preschool years. By the early school years, children absorb prevailing attitudes toward social groups from messages in their environments.
- White children show in-group favoritism and out-group prejudice by age 5 to 6. Ethnic minority children often absorb their culture's ethnic stereotypes and, as a result, show out-group favoritism. The capacity to classify the social world in multiple ways, along with growing awareness of the inappropriateness of prejudice, leads to a decline in overt prejudice in middle childhood. However, subtle prejudice often persists. Children who view personality as fixed, have overly high self-esteem, and experience a social world in which people are sorted into groups are more likely to harbor ethnic prejudices.

© MICHAEL J. DOOLITTLE/ THE IMAGE WORKS

- Long-term intergroup contact and collaboration are highly effective in reducing prejudice, and inducing children to view others' traits as malleable is also helpful. School integration—a powerful basis for combating negative ethnic and racial biases—has receded dramatically in the United States.

Understanding Conflict: Social Problem Solving **(p. 480)**

Discuss the development of social problem-solving skills, noting ways to enhance social problem solving in children.

- **Social problem-solving** skills—noticing and interpreting social cues, clarifying social goals, generating and evaluating strategies, and enacting responses—improve over early and middle childhood and predict socially competent behavior. Interventions that teach effective social problem-solving skills improve peer relations and reduce the risk of adjustment difficulties.

CHAPTER 12

"Peace Will Come One Day"

Nelma Sahinovic
12 years, Bosnia

This portrayal of a benevolent world expresses the artist's keen moral sensibilities. Human nature, family, peers, school, and culture all contribute to the cognitive, emotional, and behavioral ingredients of morality.

Reprinted with permission from the International Child Art Foundation, Washington, DC

Moral Development

Three-year-old Leisl grabbed a toy from Ava, a neighbor child who had come to play. “Give it back!” Ava cried. “It’s mine!”

Leisl’s mother bent down. “Look!” she explained. “Ava’s about to cry. She was playing with the teddy bear, and when you took it, you made her sad. Let’s give the bear back to Ava.” Gently, she freed the toy from Leisl’s hands and returned it to Ava. For a moment, Leisl looked hurt, but she soon busied herself with her blocks. A few moments later, Leisl turned to Ava. “Want some of these?” she offered generously, making a pile of blocks for Ava. “We can share!”

Now consider Leisl at age 11, reacting to a newspaper article about an elderly woman, soon to be evicted from her crumbling home because city inspectors judged it a fire and health hazard. “Look at what they’re trying to do!” exclaimed Leisl. “They’re going to throw this poor lady out of her house. You don’t just knock someone’s home down! Where’re her friends and neighbors? Why aren’t they over there fixing up that house?”

Eleven-year-old Leisl has come a long way from the preschool child just beginning to appreciate others’ rights and feelings. That beginning, however, is an important one. Preschooler Leisl’s prosocial invitation to her visiting playmate is part of an emerging picture. Accompanying gains in self-awareness and representational capacities at the end of the second year is another crowning achievement: The child becomes a moral being. Recall that around this time, empathy and sympathetic concern emerge (Chapter 10), and children soon begin to evaluate their own and others’ behavior as “good” or “bad” (Chapter 11). As children’s cognition and language develop and their social experiences broaden, they express increasingly elaborate moral thoughts accompanied by intense emotion that—as with 11-year-old Leisl—sometimes escalates to moral outrage.

In all cultures, morality is promoted by an overarching social organization that specifies rules for good conduct. At the same time, morality has roots in each major aspect of our psychological makeup:

- Morality has an *emotional component.* Powerful feelings cause us to empathize with another’s distress or to feel guilty when we are the cause of that distress.
- Morality also has an important *cognitive component.* Children’s developing social understanding enables them to make increasingly profound judgments about actions they believe to be right or wrong.
- Morality has a vital *behavioral component.* Experiencing morally relevant thoughts and feelings increases the likelihood, but does not guarantee, that people will act in accord with them.

Traditionally, these three aspects of morality have been studied separately: Biological and psychoanalytic theories focus on emotions, cognitive-developmental theory on moral thought, and social learning theory on moral behavior. Today, a growing body of research reveals that all three facets are interrelated. Still, major theories disagree on which is primary. And as we will see, the aspect a theory emphasizes has major implications for how it conceptualizes the basic trend of moral development: the shift from superficial, or externally controlled, responses to behavior based on inner standards, or moral understanding. Truly moral individuals do not merely do the right thing for the sake of social conformity or to meet the expectations of authority figures. Rather, they have developed compassionate concerns and ideals of good conduct, which they follow in a wide variety of situations.

BIOLOGY AND ENVIRONMENT: *Two Routes to Adolescent Delinquency*

CULTURAL INFLUENCES: *Impact of Ethnic and Political Violence on Children*

Our discussion of moral development begins by highlighting the strengths and limitations of the theories just mentioned in light of recent research. Next we consider the important related topic of self-control. The development of a personal resolve to keep the self from doing anything it feels like doing is crucial for translating moral commitments into action. We conclude with a discussion of the other side of self-control—the development of aggression. ■

- Describe and evaluate the biological perspective on morality.

Morality as Rooted in Human Nature

In the 1970s, biological theories of human social behavior suggested that many morally relevant behaviors and emotions have roots in our evolutionary history (Wilson, 1975). This view was supported by the work of ethologists, who observed animals aiding other members of their species, often at great personal risk (Lorenz, 1983). For example, ants, bees, and termites show extremes of self-sacrifice. Large numbers will sting or bite an animal that threatens the hive, a warlike response that often results in their own death. Dogs who breach a master's prohibition by damaging furniture or defecating indoors sometimes display intense regret, expressed as distress and submission.

Among primates, chimpanzees (who are genetically closest to humans) conform to moral-like rules, which group members enforce in one another. For example, when males attack females, they avoid using their sharp canine teeth. If a male does harm a female, the entire colony responds with a chorus of indignant barks, sometimes followed by a band of females chasing off the aggressor (de Waal, 1996). Chimps also reciprocate favors, generously grooming and sharing food with those who have done the same for them. And they engage in kind and comforting acts. Juveniles sometimes soothe frightened or injured peers, and adult females will adopt a baby that has lost its mother (Goodall, 1990). Furthermore, shortly after a physical fight, former combatants may embrace, hold hands, and groom, intensifying friendly behaviors in an apparent effort to restore their long-term relationship (de Waal, 2001, 2006). On the basis of this evidence, researchers reasoned that evolution must have made similar biologically based provisions for moral acts in humans.

Although a variety of built-in bases for morality have been posited, empathy or caring and self-sacrifice (as the above examples suggest) are of prime importance (Haidt & Kesebir, 2010). In other species, most of these acts occur within family groups, whose members have common reproductive interests. Humans, too, are biased to aid family members—helping that strengthens as genetic relatedness increases and that is particularly strong in life-and-death situations, such as entering a burning building to save a life or donating a kidney for a transplant (Neyer & Lang, 2003). But humans also have an unmatched capacity to make sacrifices for nonrelatives—by investing time and effort in helping the needy in their communities, donating generously to charities, aiding others in emergencies, and giving their lives for their country in wartime (Becker & Eagly, 2004; Van Lange et al., 2007).

Chimpanzees conform to moral-like rules, such as sharing food, and enforce those rules in one another. Researchers speculate that moral acts in humans have a similar biological basis.

© STEVE BLOOM IMAGES/ALAMY

Evolutionary theorists speculate that our unique capacity to act prosocially toward genetic strangers originated several million years ago, in the small hunting-and-gathering bands—including both kin and nonkin—in which we spent 95 percent of our evolutionary history. To limit selfishness (which can quickly undermine group functioning), humans developed informal systems of social exchange, in which they acted benevolently toward others with the expectation that others might do the same for them in the future. These reciprocal exchanges (as noted earlier) occur in other species, especially primates, but they are far more common, varied, and highly developed in humans (Van Vugt & Van Lange, 2006). The willingness of many members of a group to aid others and engage in self-sacrifice ensures that the majority will survive and reproduce. Under these conditions, traits that foster altruism undergo natural selection, becoming increasingly prominent in succeeding generations.

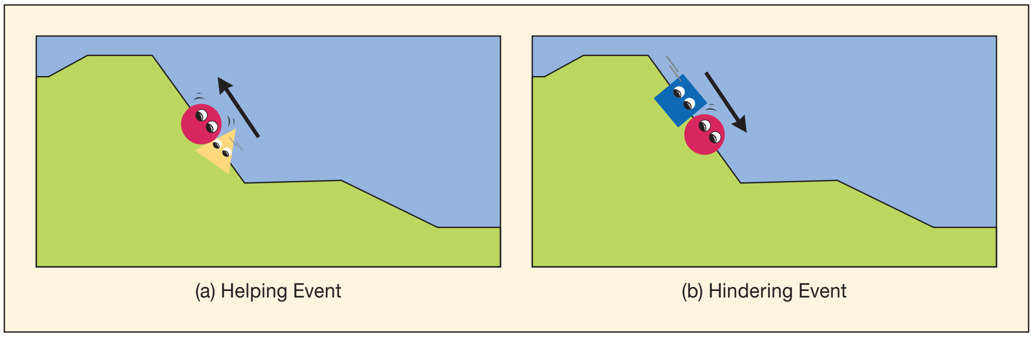
How might genes encourage prosocial acts and, thereby, promote survival of the species? Many researchers believe that prewired emotional reactions are involved (de Waal, 2006; Haidt, 2001, 2003; Hoffman, 2000; Trivers, 1971). In Chapter 10, we noted that newborns cry when they hear another baby cry, a possible precursor of empathy. As Figure 12.1 illustrates, 6-month-olds' reaching behaviors convey a preference for an individual who helps over one who hinders others—an attitude present so early that the investigators speculated it is built in (Hamlin, Wynn, & Bloom, 2007). As toddlers approach age 2, they show clear empathic concern, and they begin experiencing self-conscious emotions, which greatly enhance their responsiveness to social expectations.

© MARTIN SCHOELLER/AUGUST

The unique human capacity to act prosocially toward nonrelatives is believed to have originated several million years ago in small hunting-and-gathering bands. Here, gatherers of the Hadza people of Tanzania pick berries to share among families at their camp.

Researchers have identified areas within the prefrontal cortex (the ventromedial area, located just behind the bridge of the nose, and the orbitofrontal area, resting above the orbits of the eyes) that are vital for emotional responsiveness to the suffering of others and to one's own misdeeds. Functioning of the prefrontal cortex improves over the first two years, preceding children's increased empathic concern (see Chapter 5). Furthermore, adults with damage to these areas rarely react with empathy to others' distress, do poorly on tests of social reasoning, and are relatively unconcerned about conforming to social norms (Damasio, 1994; Eslinger et al., 2007; Moll, de Oliveira-Souza, & Zahn, 2009). Early-occurring ventromedial and orbitofrontal damage severely disrupts social learning, resulting in extreme antisocial behavior (Anderson et al., 1999; Eslinger, 1998). And EEG and fMRI research reveals that psychopaths, who inflict harm on others without any trace of empathy or guilt, show reduced activity in these areas (Raine, 1997).

Humans' elaborate mirror neuron systems are also believed to support empathic responding (see Chapter 4, page 146). fMRI evidence indicates that self-experienced pain and observations of another's facial reactions to pain activate corresponding areas in the cerebral cortex (Botvinick et al., 2005). Even the intensity of pain experienced by another is reflected in heightened cortical activity—a response that correlates positively with observers' self-reported empathy (Budell, Jackson, & Rainville, 2010; Saarela et al., 2007).



(a) Helping Event

(b) Hindering Event

FIGURE 12.1 **Infants prefer an individual who helps to one who hinders others.** Researchers exposed 6- and 10-month-olds to a scene in which a climber (red circle) repeatedly tried to climb a hill. After the third attempt, the infants saw alternating instances of helping and hindering events: (a) A helper (yellow triangle) aided the climber by pushing it from behind, or (b) a hinderer (blue square) pushed the climber down the hill. Then the infants were presented with the helper and the hinderer and encouraged to choose between the two. The overwhelming majority—100 percent of 6-month-olds and 88 percent of 10-month-olds—reached for the helper. The researchers concluded that babies have a built-in preference for individuals who aid others. Others, however, claim that social experiences during the first six months offer many relevant learning opportunities. (From J. K. Hamlin, K. Wynn, & P. Bloom, 2007, "Social Evaluation by Preverbal Infants," *Nature, 450,* p. 557. Copyright © 2007, Rights Managed by Nature Publishing Group. Reprinted by permission from Macmillan Publishers Ltd.)

But biological theories of morality as simply a matter of feelings rooted in human nature have limitations. Recall from Chapter 10 that empathy, sympathy, pride, guilt, and other self-conscious emotions require strong caregiving supports to develop, and their mature expression depends on cognitive development. Furthermore, although emotion is one basis for moral action, it is not a complete account. For example, most of us would question the behavior of a parent who decides not to take a sick child to the doctor out of empathy with the child's fear and anxiety.

Still, the biological perspective reminds us of morality's adaptive value. Because of the necessity for group living, humans have evolved an elaborate brain-based moral substrate that counteracts self-centered motives and promotes concern for others.

- Describe and evaluate the psychoanalytic perspective on moral development.
- Describe and evaluate the social learning perspective on moral development.
- Cite central features of the cognitive-developmental approach to moral development.

Morality as the Adoption of Societal Norms

The two perspectives we are about to discuss—psychoanalytic theory and social learning theory—offer different accounts of how children become moral beings. Yet both regard moral development as a matter of **internalization:** adopting societal standards for right action as one's own. In other words, both focus on how morality moves from society to individual—how children acquire norms, or prescriptions for good conduct, widely held by members of their social group.

Our consideration of these theories will reveal that several factors jointly affect the child's willingness to adopt societal standards:

- Parental style of discipline, which varies with the type of misdeed
- The child's characteristics, including age and temperament
- The parent's characteristics
- The child's view of both the misdeed and the reasonableness of parental demands

As this list indicates, internalization results from a combination of influences within the child and the rearing environment. When the process goes well, external forces foster the child's positive inclinations and counteract the child's negative inclinations (Turiel, 2006). In the following sections, we will see many examples of this idea.

Psychoanalytic Theory and the Role of Guilt

Recall from Chapter 1 that according to Sigmund Freud, morality emerges between ages 3 and 6, the period of the well-known Oedipus and Electra conflicts. Young children desire to possess the parent of the other sex, but they abandon this wish because they fear punishment and loss of parental love. To maintain their parents' affection, children form a *superego,* or conscience, by *identifying* with the same-sex parent, whose moral standards they adopt. Finally, children turn the hostility previously aimed at the same-sex parent toward themselves, which evokes painful feelings of guilt each time they disobey the superego (Freud, 1925/1961). Moral development, Freud believed, is largely complete by age 5 to 6.

Today, most researchers disagree with Freud's ideas about conscience development. First, his view of guilt as a hostile impulse redirected toward the self is no longer accepted. Rather, school-age children experience guilt when they intentionally engage in acts that harm others and feel personally responsible for the outcome (see Chapter 10). Second, Freud assumed that fear of punishment and loss of parental love motivate conscience formation. Yet children whose parents frequently use threats, commands, or physical force tend to violate standards often and feel little guilt, whereas parental warmth and responsiveness predict greater guilt following transgressions (Kochanska et al., 2002, 2005, 2008). And if a parent withdraws love after misbehavior—for example, refuses to speak to or states a dislike for the child—children often respond with high levels of self-blame, thinking "I'm no good" or "Nobody loves me." Eventually, to protect themselves from overwhelming guilt, these children may deny the emotion and, as a result, also develop a weak conscience (Kochanska, 1991; Zahn-Waxler et al., 1990).

Inductive Discipline In contrast, conscience formation is promoted by a type of discipline called **induction,** in which an adult helps the child notice others' feelings by pointing out the effects of the child's misbehavior on others, especially noting their distress and making clear that the child caused it. For example, to a young preschool child, the parent might say, "She's crying because you won't give back her teddy bear," as Leisl's mother did in the introduction to this chapter. To older preschoolers, parents can explain why the child's action was harmful, perhaps by referring to the other person's intentions: "Don't yell at him. That makes him feel sad. He was trying to help you!" And with further cognitive advances, more subtle psychological explanations are possible: "He felt proud of his tower, and you hurt his feelings by knocking it down" (Hoffman, 2000).

When generally warm parents provide explanations that match the child's capacity to understand, while firmly insisting that the child listen and comply, induction is effective as early as age 2. Preschoolers whose parents use this approach are more likely to refrain from wrongdoing, confess and repair damages after misdeeds (as Leisl did when she invited Ava to play with her blocks), and display prosocial behavior (Kerr et al., 2004; Volling, Mahoney, & Rauer, 2009; Zahn-Waxler, Radke-Yarrow, & King, 1979).

© LAURA DWIGHT PHOTOGRAPHY

A teacher explains to a child how his misbehavior affects others, calling attention to his classmate's distress. Inductive discipline encourages empathy and sympathetic concern, which motivate prosocial behavior.

Induction remains powerfully effective at older ages. In one study, the more adolescents reported that their mothers used induction (as opposed to power assertion and love withdrawal), the stronger their **moral identity**—endorsement of moral values (such as fairness, kindness, and generosity) as central to their self-concept (Patrick & Gibbs, 2011). Adolescents also reacted to induction with greater guilt and emotional acceptance, and they more often viewed it as a fair and appropriate parental response. Maternal expressions of disappointed expectations (emphasizing that the teenager is capable of a higher moral standard) tended to co-occur with induction and contributed to its prediction of moral identity.

The success of induction may lie in its power to motivate active commitment to moral norms, in the following ways:

- Induction gives children information about how to behave that they can use in future situations.
- By emphasizing the impact of the child's actions on others, induction encourages empathy and sympathetic concern, which motivate prosocial behavior (Krevans & Gibbs, 1996).
- Giving children reasons for changing their behavior encourages them to adopt moral standards because those standards make sense.
- Children who consistently experience induction may form a *script* for the negative emotional consequences of harming others: Child causes harm, inductive message points out harm, child feels empathy for victim, child makes amends (Hoffman, 2000). The script deters future transgressions.
- Children and adolescents who view discipline as fair are more likely to listen to, accept, and internalize the parent's message (Bugental & Grusec, 2006). And as teenagers increasingly mention moral qualities in their self-descriptions (see page 459 in Chapter 11), parental expressions of disappointed expectations may strengthen the impact of induction by highlighting the discrepancy between the young person's actions and self-definition.

In contrast, discipline that relies too heavily on threats of punishment or withdrawal of love makes children and adolescents so angry or anxious and frightened that they cannot think clearly enough to figure out what they should do. As a result, these practices do not get children to internalize moral norms, and—as noted earlier—also interfere with empathy and prosocial responding (Eisenberg, Fabes, & Spinrad, 2006; Padilla-Walker, 2008). Nevertheless, warnings, disapproval, and commands are sometimes necessary to get an unruly child to listen to an inductive message (Grusec, 2006).

LOOK and LISTEN

Provide several older school-age children and adolescents with three different examples of parental responses to a child's transgression against another: induction, power assertion, and love withdrawal. Ask the participants to judge the fairness of each form of discipline and to describe how they would feel after experiencing it.

© ONOKY-PHOTONONSTOP/ALAMY

When children are impulsive and low in anxiety, a secure attachment relationship motivates conscience development. This preschooler wants to follow parental rules to preserve an affectionate, supportive relationship with her father.

The Child's Contribution Although good discipline is crucial for conscience development, children's characteristics affect the success of parenting techniques. For example, in Chapter 10 we noted that empathy is moderately heritable. More empathic children require less power assertion and are more responsive to induction.

Temperament is also influential. Mild, patient tactics—requests, suggestions, and explanations—are sufficient to prompt guilt reactions and conscience development in anxious, fearful preschoolers (Kochanska et al., 2002). But with fearless, impulsive children, gentle discipline has little impact. Power assertion also works poorly: It undermines the child's capacity for effortful control, which strongly predicts moral internalization, empathy, sympathy, and prosocial behavior (Kochanska & Aksan, 2006; Kochanska & Knaack, 2003). Parents of impulsive children can foster conscience development by building a warm, affectionate relationship that promotes secure attachment and by combining firm correction of misbehavior with induction (Kochanska, Aksan, & Joy, 2007). When children are so low in anxiety that parental interventions cause them little discomfort, a close parent–child bond provides an alternative foundation for morality. It motivates children to listen to parents' inductions and follow their rules as a means of preserving an affectionate, supportive relationship.

In sum, to foster early moral development, parents must tailor their disciplinary strategies to their child's personality. Does this remind you of goodness of fit, discussed in Chapter 10? Return to page 426 to review this idea.

The Role of Guilt Although little support exists for Freudian ideas about conscience development, Freud was correct that guilt is an important motivator of moral action. By the end of toddlerhood, guilt reactions are evident, and preschoolers' assertions to others reveal that they have internalized the parent's moral voice: "Didn't you hear my mommy? We'd better not play with these toys" (Thompson, 2009).

Inducing *empathy-based guilt* (expressions of personal responsibility and regret, such as "I'm sorry I hurt him") by explaining that the child's behavior is causing someone distress is a means of influencing children without using coercion. Empathy-based guilt reactions are associated with stopping harmful actions, repairing damage caused by misdeeds, and engaging in future prosocial behavior (Baumeister, 1998; Eisenberg, Eggum, & Edwards, 2010). At the same time, parents must help children deal with guilt feelings constructively—by guiding them to make up for immoral behavior rather than minimizing or excusing it (Bybee, Merisca, & Velasco, 1998).

But contrary to what Freud believed, guilt is not the only force that compels us to act morally. Nor is moral development complete by the end of early childhood. Rather, it is a gradual process, beginning in the preschool years and extending into adulthood.

Social Learning Theory

The social learning perspective does not regard morality as a special human activity with a unique course of development. Rather, moral behavior is acquired just like any other set of responses: through reinforcement and modeling.

Importance of Modeling Operant conditioning—reinforcement for good behavior with approval, affection, and other rewards—is not enough for children to acquire moral responses. For a behavior to be reinforced, it must first occur spontaneously. Yet many prosocial acts, such as sharing, helping, or comforting an unhappy playmate, occur so rarely at first that reinforcement cannot explain their rapid development in early childhood. Rather, social learning theorists believe that children learn to behave morally largely through *modeling*—observing and imitating adults who demonstrate appropriate behavior (Bandura, 1977; Grusec, 1988). Once children acquire a moral response, such as sharing or telling the truth, reinforcement in the form of praising the act ("That was a very nice thing to do") or the child's character ("You're a very kind and considerate boy") increases its frequency (Mills & Grusec, 1989).

Many studies show that having helpful or generous models increases young children's prosocial responses. And certain characteristics of the model affect children's willingness to imitate:

- *Warmth and responsiveness.* Preschoolers are more likely to copy the prosocial actions of an adult who is warm and responsive than those of a cold, distant adult (Yarrow, Scott, & Waxler, 1973). Warmth seems to make children more attentive and receptive to the model and is itself an example of a prosocial response.
- *Competence and power.* Children admire and therefore tend to imitate competent, powerful models—especially older peers and adults (Bandura, 1977).
- *Consistency between assertions and behavior.* When models say one thing and do another—for example, announce that "it's important to help others" but rarely engage in helpful acts—children generally choose the most lenient standard of behavior that adults demonstrate (Mischel & Liebert, 1966).

© LAURA DWIGHT PHOTOGRAPHY

Modeling helpful behavior is especially influential in the early years. This 3-year-old watches attentively as his father demonstrates how to fold laundry.

Models are most influential in the early years. In one study, toddlers' eager, willing imitation of their mothers' behavior predicted moral conduct (not cheating in a game) and guilt following transgressions at age 3 (Forman, Aksan, & Kochanska, 2004). At the end of early childhood, children who have had consistent exposure to caring adults tend to behave prosocially whether or not a model is present: They have internalized prosocial rules from repeated observations and encouragement by others (Mussen & Eisenberg-Berg, 1977).

Effects of Punishment Many parents are aware that angrily yelling at, slapping, and spanking children are ineffective disciplinary tactics. A sharp reprimand or physical force to restrain or move a child is justified when immediate obedience is necessary—for example, when a 3-year-old is about to run into the street. In fact, parents are most likely to use forceful methods under these conditions. But to foster long-term goals, such as acting kindly toward others, they tend to rely on warmth and reasoning (Kuczynski, 1984). And in response to very serious transgressions, such as lying or stealing, they often combine power assertion with reasoning (Grusec, 2006; Grusec & Goodnow, 1994).

Frequent punishment, however, promotes only immediate compliance, not lasting changes in behavior. Children who are repeatedly criticized, shouted at, or hit are likely to display the unacceptable response again as soon as adults are out of sight. The more harsh threats, angry physical control (yanking an object from the child, handling the child roughly), and physical punishment children experience, the more likely they are to develop serious, lasting mental health problems. These include weak internalization of moral rules; depression, aggression, antisocial behavior, and poor academic performance in childhood and adolescence; and depression, alcohol abuse, criminality, and partner and child abuse in adulthood (Afifi et al., 2006; Bender et al., 2007; Gershoff, 2002a; Kochanska, Aksan, & Nichols, 2003; Lynch et al., 2006).

Harsh punishment has several undesirable side effects:

- Parents often spank in response to children's aggression (Holden, Coleman, & Schmidt, 1995). Yet the punishment itself models aggression!
- Harshly treated children react with anger, resentment, and a chronic sense of being personally threatened, which prompts a focus on the self's distress rather than a sympathetic orientation to others' needs (see Chapter 10, page 417).
- Children who are frequently punished develop a more conflict-ridden and less supportive parent–child relationship and also learn to avoid the punitive parent (McLoyd &

Smith, 2002; Shaw, Lacourse, & Nagin, 2005). Consequently, the parent has little opportunity to teach desirable behaviors.

- By stopping children's misbehavior temporarily, harsh punishment gives adults immediate relief, reinforcing them for using coercive discipline. For this reason, a punitive adult is likely to punish with greater frequency over time, a course of action that can spiral into serious abuse.
- Children, adolescents, and adults whose parents used *corporal punishment*—the use of physical force to inflict pain but not injury—are more accepting of such discipline (Deater-Deckard et al., 2003; Vitrup & Holden, 2010). In this way, use of physical punishment may transfer to the next generation.

Although corporal punishment spans the SES spectrum, its frequency and harshness are elevated among less educated, economically disadvantaged parents (Giles-Sims, Straus, & Sugarman, 1995; Lansford et al., 2004, 2009). And consistently, parents with conflict-ridden marriages and with mental health problems (who are emotionally reactive, depressed, or aggressive) are more likely to be punitive and also to have hard-to-manage children, whose disobedience evokes more parental harshness (Berlin et al., 2009; Erath et al., 2006; Knafo & Plomin, 2006; Taylor et al., 2010). These parent–child similarities suggest that heredity contributes to the link between punitive discipline and children's adjustment difficulties. But heredity is not a complete explanation. **TAKE A MOMENT...** Return to page 124 in Chapter 3 to review findings indicating that good parenting can shield children who are genetically at risk for aggression and antisocial activity from developing those behaviors.

Furthermore, in a longitudinal study extending from 15 months to 3 years, early corporal punishment predicted emotional and behavior problems in children of diverse temperaments (Mulvaney & Mebert, 2007). Negative outcomes were simply more pronounced among temperamentally difficult children. Other longitudinal findings reveal a similar link between physical punishment and later child and adolescent aggression, even after child, parenting, and family characteristics that might otherwise account for the relationship were controlled (Berlin et al., 2009; Lansford et al., 2009, 2011; Taylor et al., 2010).

Ethnographic evidence indicates that corporal punishment increases in societies with autocratic political decision making and cultures of violence (Ember & Ember, 2005). Yet among countries differing widely in characteristics—including economic well-being, educational attainment of the population, and individualistic versus collectivist orientations—increased use of yelling, scolding, and corporal punishment is positively associated with child anxiety and aggression (Gershoff et al., 2010; Lansford et al., 2005). The corporal punishment–child anxiety/aggression associations are slightly less strong in countries where the practice is widely accepted, perhaps because parents in those nations apply it in a milder, less impulsive manner. But negative child outcomes nevertheless persist.

In view of these findings, the widespread use of corporal punishment by American parents is cause for concern. A survey of a nationally representative sample of U.S. households revealed that although corporal punishment increases from infancy to age 5 and then declines, the percentage of parents who use it is high at all ages (see Figure 12.2). Most parents report physically punishing their children only occasionally—on average, once or twice per month. Still, an alarming 35 to 50 percent of U.S. infants—who are not yet capable of complying with adult directives—get spanked or hit (Oldershaw, 2002). And more than one-fourth of physically punishing U.S. parents report having used a hard object, such as a brush or a belt (Gershoff, 2002b).

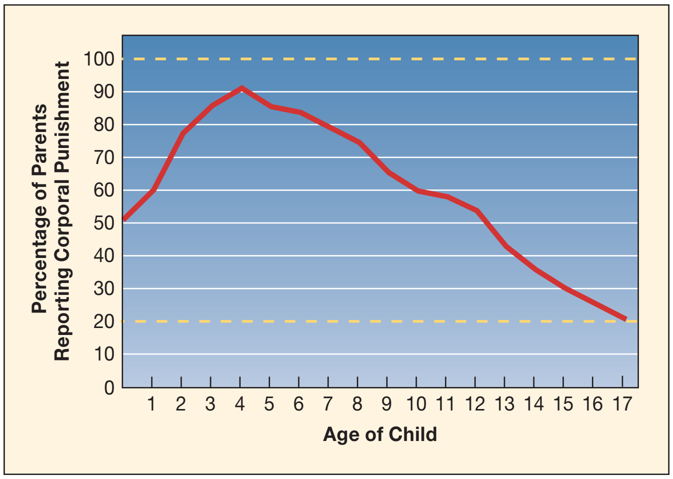


FIGURE 12.2 **Prevalence of corporal punishment by child's age.** Estimates are based on the percentage of parents in a nationally representative U.S. sample of nearly 1,000 who reported one or more instances of spanking, slapping, pinching, shaking, or hitting with a hard object in the past year. Physical punishment increases sharply during early childhood and then declines, but it is high at all ages. (From M. A. Straus & J. H. Stewart, 1999, "Corporal Punishment by American Parents: National Data on Prevalence, Chronicity, Severity, and Duration in Relation to Child and Family Characteristics," *Clinical Child and Family Psychology Review, 2,* p. 59. Adapted with kind permission from Springer Science and Business Media and Murray A. Straus.)

CULTURAL INFLUENCES

Ethnic Differences in the Consequences of Physical Punishment

In an African-American community, six elders, all of whom had volunteered to serve as mentors for parents facing child-rearing challenges, met to discuss parenting issues at a social service agency. Their attitudes toward discipline were strikingly different from those of the white social workers who had brought them together. Each elder argued that successful child rearing required appropriate physical tactics. At the same time, they voiced strong disapproval of screaming or cursing at children, calling such out-of-control parental behavior "abusive." Ruth, the oldest and most respected member of the group, characterized good parenting as a complex combination of warmth, teaching, talking nicely, and disciplining physically. She related how an older neighbor advised her to handle her own children when she was a young parent:

> She said to me, says don't scream . . . talk to them real nice and sweet and when they do something ugly and you don't like it . . . she say you get a nice little switch and you won't have any trouble with them and from that day . . . that's the way I raised 'em. (Mosby et al., 1999, pp. 511–512)

The others chimed in, emphasizing *mild* punishment: "Just tap 'em a little bit." "When you do things like [get too harsh] you're wronging yourself" (Mosby et al., 1999, pp. 511–512).

Although corporal punishment is linked to a wide array of negative child outcomes, exceptions do exist. In one longitudinal study, researchers followed several hundred families for 12 years, collecting information from mothers on disciplinary strategies in early and middle childhood and from both mothers and their children on problem behaviors in adolescence. Even after many child and family characteristics were controlled, the findings were striking: In Caucasian-American families, physical punishment was positively associated with adolescent aggression and antisocial behavior. In African-American families, by contrast, the more mothers had disciplined physically in childhood, the less their teenagers displayed angry, acting-out behavior and got in trouble at school and with the police (Lansford et al., 2004).

© ELLEN B. SENISI PHOTOGRAPHY

African-American parents' disciplinary tactics often include mild physical punishment. Because the practice is culturally approved and delivered in a context of parental warmth, children may view it as an effort to encourage maturity.

African-American and Caucasian-American parents seem to mete out physical punishment differently. In black families, such discipline is typically culturally approved, mild, delivered in a context of parental warmth, and aimed at helping children become responsible adults. White parents, in contrast, usually consider physical punishment to be wrong, so when they resort to it, they are often highly agitated and rejecting of the child (Dodge, McLoyd, & Lansford, 2006). As a result, most black children may view spanking as a practice carried out with their best interests in mind, whereas white children may regard it as an "act of personal aggression" (Gunnoe & Mariner, 1997, p. 768).

In support of this view, when several thousand ethnically diverse children were followed from preschool through the early school years, spanking was associated with a rise in behavior problems if parents were cold and rejecting but not if they were warm and supportive (McLoyd & Smith, 2002). In another study, spanking predicted depressive symptoms only among a minority of African-American children whose mothers disapproved of the practice and, as a result, tended to use it when they were highly angry and frustrated (McLoyd et al., 2007).

These findings are not an endorsement of physical punishment. Other forms of discipline, including time out, withdrawal of privileges, and the positive strategies listed on page 495, are far more effective. But it is noteworthy that the meaning and impact of physical discipline vary sharply with its intensity level, context of warmth and support, and cultural approval.

A prevailing American belief is that corporal punishment, if implemented by caring parents, is harmless, perhaps even beneficial. But as the Cultural Influences box above reveals, this assumption is valid only under conditions of limited use in certain social contexts.

Alternatives to Harsh Punishment Alternatives to criticism, slaps, and spankings can help parents avoid the undesirable effects of punishment. A technique called **time out** involves removing children from the immediate setting—for example, by sending them to their rooms—until they are ready to act appropriately. When a child is out of control, a few minutes in time out can be enough to change behavior while also giving angry parents time to cool off (Morawska & Sanders, 2011). Another approach is *withdrawal of privileges,* such as playing outside or watching a favorite TV program. Like time out, removing privileges allows parents to avoid using harsh techniques that can easily intensify into violence.

Although its usefulness is limited, punishment can play a valuable role in moral development. Earlier we noted that mild warnings and disapproval are occasionally necessary to get the child to attend to the parent's inductive message. When parents do decide to use punishment, they can increase its effectiveness in three ways:

- *Consistency.* Permitting children to act inappropriately on some occasions but scolding them on others confuses them, and the unacceptable act persists (Acker & O'Leary, 1996).
- *A warm parent–child relationship.* Children of involved, caring parents find the interruption in parental affection that accompanies punishment especially unpleasant. They want to regain parental warmth and approval as quickly as possible.
- *Explanations.* Providing reasons for mild punishment helps children relate the misdeed to expectations for future behavior. This approach leads to a far greater reduction in misbehavior than using punishment alone (Larzelere et al., 1996).

Positive Relationships, Positive Parenting The most effective forms of discipline encourage good conduct—by building a mutually respectful bond with the child, letting the child know ahead of time how to act, and praising mature behavior (Zahn-Waxler & Robinson, 1995). When sensitivity, cooperation, and shared positive emotion are evident in joint activities between parents and their toddlers or preschoolers, children show firmer conscience development—expressing empathy after transgressions, behaving responsibly, playing fairly in games, and considering others' welfare (Kochanska et al., 2005, 2008). An early, mutually responsive, pleasurable parent–child tie continues to predict a firmer conscience into the early school years (Kochanska & Murray, 2000). Parent–child closeness leads children to heed parental demands because the child feels a sense of commitment to the relationship.

Consult Applying What We Know on the following page for ways to parent positively. Parents who use these strategies focus on long-term social and life skills—cooperation, problem solving, and consideration for others. As a result, they greatly reduce the need for punishment.

With parental guidance and encouragement, these sisters follow their route on a map during a long car trip. This positive parenting strategy keeps them constructively involved and reduces the likelihood of misbehavior.

Limitations of "Morality as the Adoption of Societal Norms" Perspective

As previously noted, both psychoanalytic and social learning theories view moral development as a process of adopting societal norms. Personal commitment to societal standards of good conduct is an essential aspect of moral development. Without an internalized, shared moral code and the cultivation of empathy through parental warmth and inductive discipline, people would disregard one another's rights whenever their desires conflicted and would transgress whenever they were unobserved.

But theories that regard morality as entirely a matter of internalizing norms have been criticized because prevailing standards may be at odds with important ethical principles and humanitarian goals. Under these conditions, deliberate violation of norms is not immoral but justifiable and courageous (Appiah, 2010). **TAKE A MOMENT...** Think about historical figures who rose to greatness because they refused to accept certain societal norms. Abraham Lincoln's opposition to slavery, Susan B. Anthony's leadership in the crusade for women's suffrage, and Martin Luther King Jr.'s campaign to end racial prejudice are examples. Can you name others?

With respect to children, parental concern about internalization of societal norms is often accompanied by other goals. At times, parents may accept noncompliance if the child provides a reasonable justification (Kuczynski & Hildebrandt, 1997). Consider a boy who violates a

APPLYING WHAT WE KNOW

Positive Parenting

PRACTICE	EXPLANATION
Use transgressions as opportunities to teach.	When a child engages in harmful or unsafe behavior, intervene firmly, and then use induction, which motivates children to make amends and behave prosocially.
Reduce opportunities for misbehavior.	On long car trips, bring back-seat activities that relieve children's restlessness. At the supermarket, converse with children and let them help with shopping. As a result, children learn to occupy themselves constructively when options are limited.
Provide reasons for rules.	When children appreciate that rules are rational, not arbitrary, they are more likely to strive to follow the rules.
Arrange for children to participate in family routines and duties.	By joining with adults in preparing a meal, washing dishes, or raking leaves, children develop a sense of responsible participation in family and community life and acquire many practical skills.
When children are obstinate, try compromising and problem solving.	When a child refuses to obey, express understanding of the child's feelings ("I know it's not fun to clean up"), suggest a compromise ("You put those away, I'll take care of these"), and help the child think of ways to avoid the problem in the future. Responding firmly but kindly and respectfully increases the likelihood of willing cooperation.
Encourage mature behavior.	Express confidence in children's capacity to learn and appreciation for effort and cooperation: "You gave that your best!" "Thanks for helping!" Adult encouragement fosters pride and satisfaction in succeeding, thereby inspiring children to improve further.
Be sensitive to children's physical and emotional resources.	When children are tired, ill, or bored, they are likely to engage in attention-getting, disorganized, or otherwise improper behavior as a reaction to discomfort. In these instances, meeting the child's needs makes more sense than disciplining.

parental prohibition by cutting a cake reserved for a family celebration and giving a piece to a hungry playmate. As the parent begins to reprimand, the boy explains that the playmate had not eaten all day and that the refrigerator was nearly empty, leaving no alternative. In this instance, many parents would value the morality of the boy's claims.

Cognitive-developmental theorists believe that neither identification with parents nor teaching, modeling, and reinforcement are the major means through which children become moral. The cognitive-developmental approach assumes that individuals, rather than internalizing existing rules and expectations, develop morally through **construction**—actively attending to and interrelating multiple perspectives on situations in which social conflicts arise and thereby attaining new moral understandings. In other words, children make moral evaluations and decisions on the basis of concepts they construct about justice and fairness. As these concepts become increasingly adequate with age, children arrive at a deeper understanding of morality—as something that *must be true* in the social world, just as conservation *must be true* in the physical world (Gibbs, 1991, 2010).

In sum, the cognitive-developmental position on morality is unique in its view of the child as a thinking moral being who wonders about right and wrong and searches for moral truth. These theorists regard changes in children's reasoning as the heart of moral development.

© DANITA DELIMONT/ALAMY

Sharing a fruit, these playmates of the Shuar people of Ecuador also reflect on when, with whom, and why they ought to share. According to the cognitive-development perspective, children actively construct concepts of justice and fairness, which become increasingly adequate with age.

ASK YOURSELF

Review ■ Describe evidence indicating that many morally relevant behaviors have roots in our evolutionary history.

Connect ■ Summarize the main features of the psychoanalytic and social learning perspectives on moral development. What shortcomings do these two views share?

Apply ■ Alice and Wayne want their two young children to develop a strong, internalized conscience and to become generous, caring individuals. List some parenting practices that would foster these goals, and explain why each is effective.

Reflect ■ Did you display a strong, internalized conscience as a child? How do you think temperament, parenting practices, family living conditions, and cultural background affected your childhood moral maturity?

- Describe and evaluate Piaget's theory of moral development.
- Describe Kohlberg's theory of moral development, and discuss research on his stages.
- Describe influences on moral reasoning and its relationship to moral behavior.
- Discuss challenges to Kohlberg's theory.
- How do children distinguish moral imperatives from social conventions and matters of personal choice?

Morality as Social Understanding

According to the cognitive-developmental perspective, cognitive maturity and social experience lead to advances in moral understanding, from a superficial orientation to physical power and external consequences toward a more profound appreciation of interpersonal relationships, societal institutions, and law-making systems (Carpendale, 2009; Gibbs, 1995, 2010). As their grasp of social cooperation expands, children's ideas about what ought to be done when the needs and desires of people conflict also change, toward increasingly just, fair, and balanced solutions to moral problems.

Piaget's Theory of Moral Development

Piaget's (1932/1965) early work on children's moral judgments originally inspired the cognitive-developmental perspective. Using clinical interviews, Piaget questioned 5- to 13-year-old Swiss children about their understanding of rules in the game of marbles. He also told children stories in which characters' intentions to engage in right or wrong action differed from the consequences of their behavior. In the best known of these stories, children were asked which of two boys is naughtier, and why—well-intentioned John, who accidentally breaks 15 cups while on his way to dinner, or ill-intentioned Henry, who breaks a single cup while stealing some jam. From children's responses, Piaget identified two broad stages of moral understanding.

Heteronomous Morality (about 5 to 8 Years) *Heteronomous* means under the authority of another. As the term **heteronomous morality** suggests, children in this first stage view rules as handed down by authorities (God, parents, and teachers), as having a permanent existence, as unchangeable, and as requiring strict obedience. For example, younger children state that the rules of the game of marbles cannot be changed, explaining that "God didn't teach [the new rules]," "you couldn't play any other way," or "it would be cheating. . . . A fair rule is one that is in the game" (Piaget, 1932/1965, pp. 58, 59, 63).

According to Piaget, two factors limit children's moral understanding: (1) cognitive immaturity, especially a limited capacity to imagine other perspectives and **realism**—the tendency to view mental phenomena, including rules, as fixed external features of reality; and (2) the power of adults to insist that children comply, which promotes unquestioning respect for rules and those who enforce them. Together, egocentrism, realism, and adult power result in superficial moral understandings. Younger children think that all people view rules in the same way and that rules are absolutes rather than cooperative principles that can be modified at will. In judging an act's wrongness, they focus on impressive consequences rather than on intent to do harm. For example, in the story about John and Henry mentioned earlier, they regard John as naughtier, despite his innocent intentions, because he broke many more cups.

© MICHAEL NEWMAN/PHOTOEDIT

In Piaget's view, peer disagreements facilitate children's transition from heteronomous morality—the belief that rules are absolute and unchangeable—to a morality of cooperation: the understanding that rules are flexible, socially agreed-on principles.

Morality of Cooperation (about 9 to 10 Years and Older) Cognitive development, gradual release from adult control, and peer interaction lead children to make the transition to the second stage, **morality of cooperation,** in which they no longer view rules as fixed but see them as flexible, socially agreed-on principles that can be revised to suit the will of the majority. Piaget regarded peer disagreements as especially facilitating. Through them, children realize that people's perspectives on moral action can differ and that intentions, not concrete consequences, should serve as the basis for judging behavior.

Furthermore, as children interact as equals with peers, they learn to settle conflicts in mutually beneficial ways. Gradually, they start to use a standard of fairness called *reciprocity,* in which they express the same concern for the welfare of others as they do for themselves. Piaget found that children start with a crude, tit-for-tat understanding of reciprocity: "You scratch my back, and I'll scratch yours." This defines the beginning of the morality of cooperation. Older children and adolescents move beyond this payback morality to a grasp of the importance of mutuality of expectations, called **ideal reciprocity**—the idea expressed in the Golden Rule: "Do unto others as you would have them do unto you." Ideal reciprocity helps young people realize that rules can be reinterpreted and revised to take individual motives and circumstances into account, thereby ensuring just outcomes for all.

Evaluation of Piaget's Theory

Follow-up research indicates that Piaget's theory accurately describes the general direction of change in moral judgment. With age, outer features, such as physical damage or getting punished, give way to subtler considerations, such as the actor's intentions or the needs and desires of others. Also, much evidence confirms Piaget's conclusion that moral understanding is supported by cognitive maturity, gradual release from adult control, and peer interaction—findings we will consider when we turn to extensions of Piaget's work by Lawrence Kohlberg and his followers. Nevertheless, several aspects of Piaget's theory have been questioned because they underestimate the moral capacities of young children.

Intentions and Moral Judgments Look back at the story about John and Henry on the previous page. Because bad intentions are paired with little damage and good intentions with a great deal of damage, Piaget's method yields a conservative picture of young children's ability to appreciate intentions. When questioned about moral issues in a way that makes a person's intention as obvious as the harm done, preschool and early school-age children are capable of judging ill-intentioned people as naughtier and more deserving of punishment than well-intentioned ones (Helwig, Zelazo, & Wilson, 2001; Jones & Thomson, 2001).

As further evidence, by age 4, children clearly recognize the difference between two morally relevant intentional behaviors: truthfulness and lying. They approve of telling the truth and disapprove of lying, even when a lie remains undetected (Bussey, 1992). And by age 7 to 8—earlier than suggested by Piaget's findings—children integrate their judgments of lying and truth telling with prosocial and antisocial intentions. They evaluate very negatively certain types of truthfulness—for example, blunt statements, particularly when made in public contexts where they are especially likely to have negative social consequences (telling a friend that you don't like her drawing) (Bussey, 1999; Ma et al., 2011).

Although both Chinese and Canadian schoolchildren consider lying about antisocial acts "very naughty," Chinese children—influenced by collectivist values—more often rate lying favorably when the intention is modesty, as when a student who has thoughtfully picked up litter from the playground says, "I didn't do it" (Lee et al., 1997, 2001). Similarly,

© LONG TAO/CHINAFOTOPRESS/GETTY IMAGES

Influenced by collectivist values, Chinese schoolchildren often condone lying when the intention is modesty. These children are likely to say they won a drum-pulling competition because of group effort, even when they know that one or two children deserve most of the credit.

Chinese children are more likely than Canadian children to favor lying to support the group at the expense of the individual (saying you're sick so, as a poor singer, you won't harm your class's chances of winning a singing competition). In contrast, Canadian children more often favor lying to support the individual at the expense of the group (claiming that a friend who is a poor speller is actually a good speller because he wants to represent the class in a spelling competition) (Fu et al., 2007).

Nevertheless, an advanced understanding of the morality of intentions does await the morality of cooperation. Younger children are more likely to *center,* or focus on, salient features and consequences in their judgments, while neglecting and hence failing to integrate other important information. For example, preschoolers more often than older children evaluate lies as always wrong (Peterson, Peterson, & Seeto, 1983). They also judge lies that lead to punishment more negatively than lies that do not (Bussey, 1992). And preschoolers tend to focus on the here-and-now, ignoring a guilt-relevant prior event. Shown a series of pictures depicting one child pushing another off a playground swing and then swinging on it himself, many young children simply declare the perpetrator to be "happy, he's swinging on the swing" (Arsenio, Gold, & Adams, 2006).

Furthermore, through the early school years, children generally interpret statements of intention in a rigid, heteronomous fashion. They believe that once you say you will do something, you are obligated to follow through, even if uncontrollable circumstances (such as an accident) make it difficult or impossible to do so. By age 9 or 10, children realize that not keeping your word is much worse in some situations than in others—namely, when you are able to do so and have permitted another person to count on your actions (Mant & Perner, 1988). In sum, Piaget was partly right and partly wrong about this aspect of moral reasoning.

Reasoning About Authority Research on young children's understanding of authority reveals that they do not regard adults with the unquestioning respect Piaget assumed. Even preschoolers judge certain acts, such as hitting and stealing, to be wrong regardless of the opinions of authorities. When asked to explain, 3- and 4-year-olds express concerns about harming other people rather than obeying adult dictates (Smetana, 1981, 1985).

By age 4, children have differentiated notions about the legitimacy of authority figures, which they refine during the school years. In several studies, children in kindergarten through sixth grade were asked questions designed to assess their view of how broad an adult's authority should be. Almost all denied that adults have general authority (Laupa, 1995). For example, they rejected a principal's right to set rules and issue directives in settings other than his own school.

With respect to nonmoral concerns, such as the rules of a game, children usually base the legitimacy of authority on a person's knowledge, not on social position. And when a directive is fair and caring (for example, telling children to stop fighting or to share candy), children view it as right, regardless of who states it—a principal, a teacher, a class president, or another child. Even among Korean children, whose culture places a high value on respect for and deference to adults, 7- to 11-year-olds evaluate negatively a teacher's or principal's order to keep fighting, to steal, or to refuse to share—a response that strengthens with age (Kim, 1998; Kim & Turiel, 1996).

As these findings reveal, adult status is not required for preschool and school-age children to view someone as an authority. Knowledgeable peers or those who act to protect others' rights are regarded as just as legitimate. But in reasoning about authority, preschool and young elementary school children do tend to place greater weight than older children on power, status, and consequences for disobedience.

Stagewise Progression Many children display both heteronomous and cooperative moral reasoning, raising doubts about whether each Piagetian stage represents a general, unifying organization of moral judgment responses. But to be fair, Piaget (1932/1965) also observed this mixture in children and, therefore, regarded the two moralities as fluid, overlapping phases rather than tightly knit stages.

Finally, moral development is currently viewed as a more extended process than Piaget believed. Kohlberg's six-stage sequence, to which we turn next, identifies three stages beyond the first appearance of the morality of cooperation. Nevertheless, Kohlberg's theory is a continuation of the research begun by Piaget.

Kohlberg's Extension of Piaget's Theory

Like Piaget, Kohlberg was interested in moral reasoning and used a clinical interviewing procedure to study its development. But whereas Piaget asked children to judge and explain which of two children in a pair of stories was naughtier, Kohlberg used a more open-ended approach: He presented people with hypothetical moral dilemmas and asked what the main actor should do and why.

The Clinical Interview In Kohlberg's *Moral Judgment Interview,* individuals resolve dilemmas that present conflicts between two moral values and justify their decisions. The best-known of these, the "Heinz dilemma," pits the value of obeying the law (not stealing) against the value of human life (saving a dying person):

> In Europe, a woman was near death from cancer. There was one drug that the doctors thought might save her. A druggist in the same town had discovered it, but he was charging ten times what the drug cost him to make. The sick woman's husband, Heinz, went to everyone he knew to borrow the money, but he could only get together half of what it cost. The druggist refused to sell the drug for less or let Heinz pay later. So Heinz got desperate and broke into the man's store to steal the drug for his wife. Should Heinz have done that? Why or why not? (paraphrased from Colby et al., 1983, p. 77)

In addition to explaining their answer, participants are asked to evaluate the conflicting moral values on which the dilemma is based. Scoring of responses is highly intricate and demanding (Gibbs, Basinger, & Grime, 2003; Miller, 2007).

Kohlberg emphasized that it is *the way an individual reasons about the dilemma,* not *the content of the response* (whether or not to steal) that determines moral judgment maturity. Individuals who believe that Heinz should steal the drug and those who think he should not can be found at each of Kohlberg's first four stages. Only at the highest two stages do moral reasoning and content come together in a coherent ethical system, in which individuals agree not only on *why* certain actions are justified but also on *what* people ought to do when facing a moral dilemma (Kohlberg, Levine, & Hewer, 1983). Given a choice between obeying the law and preserving individual rights, the most advanced moral thinkers support individual rights—in the Heinz dilemma, stealing the drug to save a life.

A Questionnaire Approach For more efficient gathering and scoring of moral reasoning, researchers have devised short-answer questionnaires. The most recent, the *Sociomoral Reflection Measure–Short Form (SRM–SF),* poses 11 questions that (like Kohlberg's clinical interview) ask individuals to evaluate the importance of moral values and to reason about them. Here are four of the 11 questions:

- Let's say a friend of yours needs help and may even die, and you're the only person who can save him or her. How important is it for a person (without losing his or her own life) to save the life of a friend?
- What about saving the life of anyone? How important is it for a person (without losing his or her own life) to save the life of a stranger?
- How important is it for people not to take things that belong to other people?
- How important is it for people to obey the law? (Gibbs, Basinger, & Fuller, 1992, pp. 151–152)

After reading each question, participants rate the importance of the value it addresses (as "very important," "important," or "not important") and write a brief explanation of their rating. The explanations are coded according to a revised rendition of Kohlberg's stages. Scores on the SRM–SF correlate well with those obtained from the Moral Judgment Interview and show similar age trends, but they are far less time-consuming to obtain (Basinger, Gibbs, & Fuller, 1995; Gibbs, Basinger, & Grime, 2003; Gibbs et al., 2007).

Kohlberg's Stages of Moral Understanding

In his initial investigation, Kohlberg (1958) extended the age range Piaget studied, including participants who were well into adolescence (10-, 13-, and 16-year-old boys). Then he followed the participants longitudinally, reinterviewing them at three- to four-year intervals over the next 20 years (Colby et al., 1983). Analyzing age-related changes in the boys' moral judgments, Kohlberg generated his six-stage sequence.

As with Piaget's progression of development, Kohlberg's first three stages characterize children as moving from a morality focused on outcomes to one based on ideal reciprocity. Inclusion of older adolescents yielded the fourth stage, in which young people expand their notion of ideal reciprocity to encompass societal rules and laws as vital for ensuring that people treat one another justly. Relying on moral judgment responses of a small minority of adolescents, Kohlberg extended his sequence further, positing a fifth and sixth stage. As we will see, these stages have remained infrequent in subsequent research.

Kohlberg organized his six stages into three general levels and made stronger claims than Piaget about a fixed order of moral change. In doing so, however, Kohlberg drew on characteristics that Piaget used to describe his cognitive stage sequence:

- Kohlberg regarded his moral stages as universal and invariant—a sequence of steps through which people everywhere move in a fixed order.
- He viewed each new stage as building on reasoning of the preceding stage, resulting in a more logically consistent and morally adequate concept of justice.
- He saw each stage as an organized whole—a qualitatively distinct structure of moral thought that a person applies across a wide range of situations (Colby & Kohlberg, 1987).

Furthermore, Kohlberg believed that moral understanding is promoted by the same factors Piaget thought were important for cognitive development: (1) disequilibrium, or actively grappling with moral issues and noticing weaknesses in one's current thinking; and (2) gains in perspective taking, which permit individuals to resolve moral conflicts in increasingly complex and effective ways. **TAKE A MOMENT...** As we examine Kohlberg's developmental sequence and illustrate it with responses to the Heinz dilemma, look for changes in cognition and perspective taking that each stage assumes.

If the child on the right expects a favor in return for helping her friend, she is at Kohlberg's preconventional level. If she is motivated by ideal reciprocity, as in the Golden Rule, she has advanced to the conventional level.

The Preconventional Level. At the **preconventional level,** morality is externally controlled. Children accept the rules of authority figures and judge actions by their consequences. Behaviors that result in punishment are viewed as bad, those that lead to rewards as good.

- *Stage 1: The punishment and obedience orientation.* Children at this stage, while recognizing that others may have different thoughts and feelings, still find it difficult to consider two points of view in a moral dilemma. As a result, they overlook people's intentions. Instead, they focus on fear of authority and avoidance of punishment as reasons for behaving morally.

  > *Prostealing:* "If you let your wife die, you will . . . be blamed for not spending the money to help her, and there'll be an investigation of you and the druggist for your wife's death" (Kohlberg, 1969, p. 381).
  >
  > *Antistealing:* "You shouldn't steal the drug because you'll be caught and sent to jail if you do. If you do get away, [you'd be scared that] the police would catch up with you any minute" (Kohlberg, 1969, p. 381).

- *Stage 2: The instrumental purpose orientation.* Children realize that people can have different perspectives in a moral dilemma, but at first this understanding is concrete. They view right action as flowing from self-interest and understand reciprocity as equal exchange of favors: "You do this for me, and I'll do that for you."

> *Prostealing:* "[I]f Heinz decides to risk jail to save his wife, it's his life he's risking; he can do what he wants with it. And the same goes for the druggist; it's up to him to decide what he wants to do" (Rest, 1979, p. 26).
>
> *Antistealing:* "[Heinz] is running more risk than it's worth [to save a wife who is near death]" (Rest, 1979, p. 27).

The Conventional Level At the **conventional level,** individuals continue to regard conformity to social rules as important, but not for reasons of self-interest. Rather, they believe that actively maintaining the current social system ensures positive human relationships and societal order.

- *Stage 3: The "good boy–good girl" orientation, or the morality of interpersonal cooperation.* The desire to obey rules because they promote social harmony first appears in the context of close personal ties. Stage 3 individuals want to maintain the affection and approval of friends and relatives by being a "good person"—trustworthy, loyal, respectful, helpful, and nice. The capacity to view a two-person relationship from the vantage point of an impartial, outside observer supports this new approach to morality. At this stage, the individual understands *ideal reciprocity,* as expressed in the Golden Rule.

> *Prostealing:* "No one will think you're bad if you steal the drug, but your family will think you're an inhuman husband if you don't. If you let your wife die, you'll never be able to look anyone in the face again" (Kohlberg, 1969, p. 381).
>
> *Antistealing:* "It isn't just the druggist who will think you're a criminal, everyone else will too. . . . [Y]ou'll feel bad thinking how you brought dishonor on your family and yourself" (Kohlberg, 1969, p. 381).

- *Stage 4: The social-order-maintaining orientation.* At this stage, the individual takes into account a larger perspective—that of societal laws. Moral choices no longer depend on close ties to others. Instead, rules must be enforced in the same evenhanded fashion for everyone, and each member of society has a personal duty to uphold them. The Stage 4 individual believes that laws should be obeyed because they are vital for ensuring societal order and cooperation between people.

> *Prostealing:* "Heinz has a duty to protect his wife's life; it's a vow he took in marriage. But it's wrong to steal, so he would have to take the drug with the idea of paying the druggist for it and accepting the penalty for breaking the law later."
>
> *Antistealing:* "It's a natural thing for Heinz to want to save his wife but . . . Even if his wife is dying, it's still his duty as a citizen to obey the law. . . . If everyone starts breaking the law in a jam, there'd be no civilization, just crime and violence" (Rest, 1979, p. 30).

The Postconventional or Principled Level Individuals at the **postconventional level** move beyond unquestioning support for the laws and rules of their own society. They define morality in terms of abstract principles and values that apply to all situations and societies.

- *Stage 5: The social-contract orientation.* At Stage 5, individuals regard laws and rules as flexible instruments for furthering human purposes. They can imagine alternatives to their own social order, and they emphasize fair procedures for interpreting and changing the law. When laws are consistent with individual rights and the interests of the majority, each person follows them because of a *social-contract orientation*—free and willing participation in the system because it brings about more good for people than if it did not exist.

> *Prostealing:* "Although there is a law against stealing, the law wasn't meant to violate a person's right to life. . . . If Heinz is prosecuted for stealing, the law needs to be reinterpreted to take into account situations in which it goes against people's natural right to keep on living."
>
> *Antistealing:* At this stage, there are no antistealing responses.

NO TO BULLYING

© JANINE WIEDEL PHOTOLIBRARY/ALAMY

Protestors in London march with families of teenage victims of bullying. In imagining an end to social ills, these young people convey a principled level of maturity.

- *Stage 6: The universal ethical principle orientation.* At this highest stage, right action is defined by self-chosen ethical principles of conscience that are valid for all humanity, regardless of law and social agreement. Stage 6 individuals typically mention such abstract principles as equal consideration of the claims of all human beings and respect for the worth and dignity of each person.

  Prostealing: "It doesn't make sense to put respect for property above respect for life itself. [People] could live together without private property at all. Respect for human life and personality is absolute, and accordingly [people] have a mutual duty to save one another from dying" (Rest, 1979, p. 37).

  Antistealing: At this stage, there are no antistealing responses.

Research on Kohlberg's Stages

Kohlberg's original research and other longitudinal studies using hypothetical dilemmas provide the most convincing evidence for his stage sequence. With few exceptions, individuals move through the first four stages in the predicted order (Boom, Wouters, & Keller, 2007; Colby et al., 1983; Dawson, 2002; Walker, 1989; Walker & Taylor, 1991b).

A striking finding is that development of moral reasoning, whether assessed longitudinally or cross-sectionally, with the Moral Judgment Interview or the SRM–SF, and in diverse Western industrialized or non-Western village cultures, is slow and gradual (Colby et al., 1983; Gibbs et al., 2007; Snarey, 1985). Reasoning at Stages 1 and 2 decreases from late childhood to early adolescence, while Stage 3 reasoning increases through mid-adolescence and then declines. Stage 4 reasoning rises over the teenage years until, among college-educated young adults, it is the typical response. Few people move beyond Stage 4. As noted earlier, postconventional morality is so rare that no clear evidence exists that Kohlberg's Stage 6 actually follows Stage 5.

Are Kohlberg's Stages Organized Wholes?

TAKE A MOMENT... Think of an actual moral dilemma you faced recently. How did you solve it? Did your reasoning fall at the same stage as your thinking about the Heinz dilemma? If each of Kohlberg's stages forms an organized whole, then individuals should use the same level of moral reasoning across many tasks and situations—for everyday moral problems as well as for hypothetical dilemmas. In fact, real-life conflicts, such as whether to continue helping a friend who is taking advantage of you, often elicit moral reasoning below a person's actual capacity because they involve practical considerations and mix cognition with intense emotion (Carpendale, 2000). Although adolescents and adults still mention reasoning as their most frequent strategy for resolving these dilemmas, they also refer to other strategies—talking through issues with others, relying on intuition, and calling on religious and spiritual ideas. And they report feeling drained, confused, and torn by temptation—an emotional side of moral judgment not tapped by hypothetical situations, which evoke the upper limits of moral thought because they allow reflection without the interference of personal risk (Walker, 2004).

© BOB DAEMMRICH/PHOTOEDIT

Should the student on the left continue to collaborate on an assignment with his classmate after realizing that he is doing nearly all the work? Such real-life moral dilemmas mix cognition with intense emotion.

The influence of situational factors on moral reasoning indicates that, like Piaget's cognitive and moral stages, Kohlberg's moral stages are loosely organized and overlapping. Rather than developing in a neat, stepwise fashion, people draw on a range of moral responses that vary with context. With age, this range shifts upward as less mature moral reasoning is gradually replaced by more advanced moral thought.

Cognitive Influences on Moral Reasoning

As Kohlberg anticipated, moral maturity is positively correlated with IQ, performance on Piagetian cognitive tasks, and perspective-taking skill (Krebs & Gilmore, 1982; Lickona, 1976; Selman, 1976; Walker & Hennig, 1997). Kohlberg's stage sequence also makes sense to adolescents and adults who have not studied his theory—findings that support the vital contribution of cognitive development to moral maturity. When Russian high school and Dutch university students were asked to sort statements typical of Kohlberg's stages, they tended to rank reasoning at each consecutive stage as more sophisticated. But beyond their own current stage, they had difficulty ordering statements; the higher the stage, the more participants disagreed in their rankings (Boom, Brugman, & van der Heijden, 2001).

At the same time, Kohlberg argued that cognitive and perspective-taking attainments are not sufficient to ensure moral advances, which also require reorganization of thought unique to the moral domain. But so far, the domain in which the cognitive ingredients required for more mature moral judgment first emerges—cognitive, social, or moral—remains unclear. In Chapters 6 and 7, we encountered a wealth of evidence indicating that children display more advanced reasoning on tasks with which they have more extensive experience. Young people who frequently grapple with social and moral issues may actually construct the cognitive supports for moral development directly—while reasoning about social or moral concerns (Carpendale, 2009; Gibbs, 2010).

Are There Sex Differences in Moral Reasoning?

As we have seen, real-life moral dilemmas highlight the role of emotion in moral judgment. Return to Leisl's moral reasoning in the opening to this chapter and notice how her argument focuses on caring and commitment to others. Carol Gilligan (1982) is the best-known of those who have argued that Kohlberg's theory—originally formulated on the basis of interviews with males—does not adequately represent the morality of girls and women. Gilligan believes that feminine morality emphasizes an "ethic of care" that Kohlberg's system devalues. Leisl's reasoning falls at Kohlberg's Stage 3 because it is based on mutual trust and affection. In contrast, Stages 4 to 6 emphasize justice—an abstract, rational commitment to moral ideals. According to Gilligan, a concern for others is a *different* but no less valid basis for moral judgment than a focus on impersonal rights.

Many studies have tested Gilligan's claim that Kohlberg's approach underestimates the moral maturity of females, and most do not support it (Turiel, 2006; Walker, 2006). On hypothetical dilemmas, everyday moral problems, and the SMR–SF, adolescent and adult females display reasoning at the same stage as their male counterparts and often at a higher stage. Themes of justice and caring appear in the responses of both sexes, and when girls do raise interpersonal concerns, they are not downgraded in Kohlberg's system (Jaffee & Hyde, 2000; Walker, 1995). Rather, many studies report that girls shift from Stage 2 to Stage 3 reasoning earlier than boys (Gibbs et al., 2007). These findings suggest that although Kohlberg emphasized justice rather than caring as the highest of moral ideals, his theory taps both sets of values.

© TERRY HARRIS JUST GREECE PHOTO LIBRARY/ALAMY

This teenager takes pleasure in helping her grandmother with everyday tasks. Adolescents of both sexes express themes of justice and caring in their moral responses, but females appear to emphasize care, especially when reasoning about real-life dilemmas.

Nevertheless, some evidence indicates that although the morality of males and females includes both orientations, females tend to stress care, or empathic perspective taking, whereas males either stress justice or focus equally on justice and care (Jaffee & Hyde, 2000; Wark & Krebs, 1996; Weisz & Black, 2002). This difference in emphasis, which appears more often in real life than in hypothetical dilemmas, may reflect women's greater involvement in daily activities involving care and concern for others.

Indeed, both cultural and situational contexts profoundly affect use of a care orientation. In one study, U.S. and Canadian 17- to 26-year-old females showed more complex reasoning about care issues than their male counterparts. But Norwegian males were just as advanced as Norwegian females in care-based understanding (Skoe, 1998). Perhaps Norwegian culture, which explicitly endorses gender equality, induces boys and men to think deeply about interpersonal obligations. And in an Australian investigation, researchers presented university students with one of three versions of a moral dilemma, in which the main character varied in familiarity: (1) a close friend in class, (2) a person "known only vaguely" from class, or (3) a classmate whose relationship was unspecified (Ryan, David, & Reynolds, 2004). When asked whether they would permit the character who was in danger of failing the course to borrow a copy of their recently completed assignment despite risk of cheating, both male and female participants gave more care responses when considering a close friend than a socially distant classmate. As Figure 12.3 shows, gender differences emerged only in the unspecified condition, where women—who tend to forge closer relationships—may have assumed greater familiarity.

In sum, current evidence indicates that justice and caring are not gender-specific moralities. Perhaps Piaget (1932/1965) himself said it best: "Between the more refined forms of justice . . . and love properly so called, there is no longer any real conflict" (p. 324).

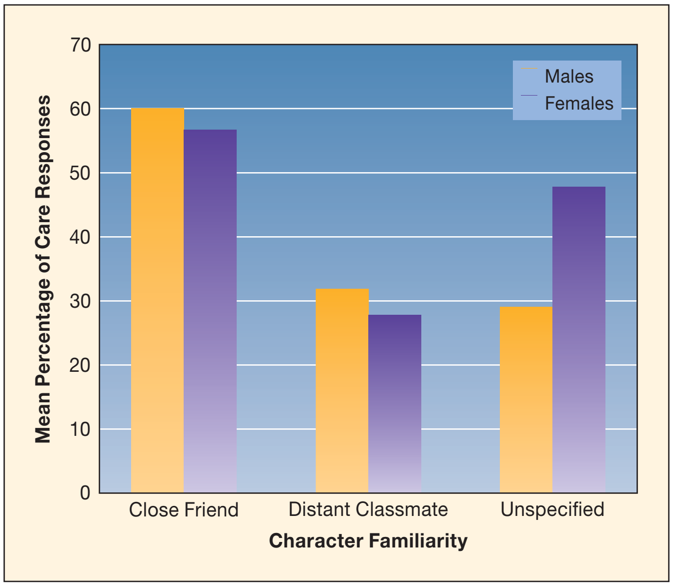

FIGURE 12.3 **Relationship of familiarity of the main character in a moral dilemma to care responses.** Both male and female university students gave more care responses when considering a close friend than a distant classmate. Sex differences appeared only in the unspecified condition, where females may have assumed greater familiarity. (From M. K. Ryan, B. David, & K. J. Reynolds, 2004, "Who Cares? The Effect of Gender and Context on the Self and Moral Reasoning," *Psychology of Women Quarterly, 28,* 246–255. Copyright © 2004 by the American Psychological Association. Influences on Moral Reasoning

Many factors affect maturity of moral reasoning, including the young person's personality and a wide range of social experiences—child-rearing practices, peer interaction, schooling, and aspects of culture. Growing evidence suggests that, as Kohlberg believed, these experiences work in two ways: They encourage young people to take the perspective of others, and they present cognitive challenges, which stimulate young people to think about moral problems in more complex ways.

Personality A flexible, open-minded approach to new information and experiences is linked to gains in moral reasoning, just as it is to identity development (Hart et al., 1998; Matsuba & Walker, 1998). Because open-minded young people are more socially skilled, they have more opportunities for social participation. A richer social life enhances exposure to others' perspectives, and open-mindedness helps adolescents derive moral insights from that exposure. In contrast, adolescents who have difficulty adapting to new experiences are less likely to be interested in others' moral ideas and justifications.

Child-Rearing Practices Child-rearing practices associated with mature moral reasoning combine warmth, exchange of ideas, and appropriate demands for maturity. Children and adolescents who gain most in moral understanding have parents who engage in moral discussions, encourage prosocial behavior, insist that others be treated respectfully and fairly, and create a supportive atmosphere by listening sensitively, asking clarifying questions, and presenting higher-level reasoning (Carlo et al., 2011; Pratt, Skoe, & Arnold, 2004; Wyatt & Carlo, 2002). In one study, 11-year-olds were asked what they thought an adult would say to justify a moral rule, such as not lying, stealing, or breaking a promise. Those with warm, demanding, communicative parents were far more likely than their agemates to point to the importance of ideal reciprocity: "I trusted you," "You wouldn't like it if I did it to you" (Leman, 2005). In contrast, when parents lecture, use threats, or make sarcastic remarks, children show little or no change in moral reasoning over time (Walker & Taylor, 1991a).

In sum, parents who facilitate moral understanding are affectionate, verbal, and rational and promote a cooperative style of family life. Notice that these are the very characteristics, discussed earlier in this chapter, that foster moral internalization in young children.

Schooling For the most part, moral reasoning advances in late adolescence and early adulthood only as long as a person remains in school (Dawson et al., 2003; Gibbs et al., 2007). Higher education introduces young people to social issues that extend beyond personal relationships to entire political and cultural groups. Consistent with this idea, college students who report more perspective-taking opportunities (for example, classes that emphasize open discussion of opinions, friendships with others of different cultural backgrounds) and who indicate that they have become more aware of social diversity tend to be advanced in moral reasoning (Comunian & Gielen, 2006; Mason & Gibbs, 1993a, 1993b).

© DANA WHITE/PHOTOEDIT

Through opportunities to discuss ideas with culturally diverse peers, these high school students gain in perspective taking and moral understanding.

Peer Interaction Research supports Piaget's belief that interaction among peers who present differing viewpoints promotes moral understanding. When young people negotiate and compromise, they realize that social life can be based on cooperation between equals rather than on authority relations (Killen & Nucci, 1995). Adolescents who report more close friendships and who more often participate in conversations with their friends are advanced in moral reasoning (Schonert-Reichl, 1999). The mutuality and intimacy of friendship, which foster decisions based on consensual agreement, may be particularly important for moral development. Furthermore, recall from Chapter 11 that intergroup contact—cross-race friendships and interactions in schools and communities—reduces racial and ethnic prejudice. It also affects young people morally, strengthening their conviction that race-based and other forms of peer exclusion are wrong (Crystal, Killen, & Ruck, 2008).

Peer discussions and role-playing of moral problems have provided the basis for interventions aimed at improving high school and college students' moral understanding. For these interventions to be effective, young people must be highly engaged—confronting, critiquing, and attempting to clarify one another's viewpoints (Berkowitz & Gibbs, 1983; Comunian & Gielen, 2006). And because moral development occurs gradually, many peer interaction sessions over weeks or months typically are needed to produce moral change.

Culture Individuals in industrialized nations move through Kohlberg's stages more rapidly and advance to a higher level than individuals in village societies, who rarely move beyond Stage 3. One explanation of these cultural differences is that in village societies, moral cooperation is based on direct relations between people and does not allow for the development of advanced moral understanding (Stages 4 to 6), which depends on appreciating the role of larger social structures, such as laws and government institutions, in resolving moral conflict (Gibbs et al., 2007).

In support of this view, in cultures where young people participate in the institutions of their society at early ages, moral reasoning is advanced. For example, on *kibbutzim,* small but technologically complex agricultural settlements in Israel, children receive training in the governance of their community in middle childhood. By third grade, they mention more concerns about societal laws and rules when discussing moral conflicts than do Israeli city-reared or U.S. children (Fuchs et al., 1986). During adolescence and adulthood, a greater percentage of kibbutz than American individuals reach Kohlberg's Stages 4 and 5 (Snarey, Reimer, & Kohlberg, 1985).

A second possible reason for cultural variation is that responses to moral dilemmas in collectivist cultures (including village societies) are often more other-directed than in Western Europe and North America (Miller, 2007). In both village and industrialized societies that highly value interdependency, statements portraying the individual as vitally connected to the social group are common. In one study, both male and female Japanese adolescents, who

© EARL & NAZIMA KOWALL/CORBIS

These adolescents living in a village in China's Pamir Mountains view moral cooperation as based on direct relations between people. Their moral reasoning is likely to emphasize a close connection between individual and group responsibility.

almost always integrate care- and justice-based reasoning, placed greater weight on caring, which they regarded as a communal responsibility. As one boy remarked, *yasashii* (kindness/gentleness) and *omoiyari* (empathy) are "something 'normal' that everyone shows" (Shimizu, 2001). Similarly, in research conducted in India, even highly educated people (expected to have attained Kohlberg's Stages 4 and 5) viewed solutions to moral dilemmas as the responsibility of the entire society, not of a single person (Miller & Bersoff, 1995).

These findings raise the question of whether Kohlberg's highest level represents a culturally specific way of thinking—one limited to Western societies that emphasize individual rights and an appeal to an inner, private conscience. At the same time, a review of over 100 studies confirmed an age-related trend consistent with Kohlberg's Stages 1 to 4 in more than 40 societies (Gibbs et al., 2007; Snarey, 1985). A common morality of justice and care is clearly evident in the responses of people from vastly different cultures.

Moral Reasoning and Behavior

A central assumption of the cognitive-developmental perspective is that moral understanding should affect moral motivation. As young people grasp the moral "logic" of human social cooperation, they are upset when this logic is violated. As a result, they realize that behaving in line with one's thinking is vital for creating and maintaining a just social world (Blasi, 1994; Gibbs, 2010). Consistent with this idea, higher-stage adolescents more often act prosocially by helping, sharing, and defending victims of injustice and by volunteering in their communities (Carlo et al., 1996, 2011; Comunian & Gielen, 2000, 2006). Also, they less often engage in cheating, aggression, and other antisocial or delinquent behaviors (Raaijmakers, Engels, & Van Hoof, 2005; Stams et al., 2006).

Yet the connection between more mature moral reasoning and action is only modest. As we have seen, moral behavior is influenced by many factors besides cognition, including the emotions of empathy, sympathy, and guilt; individual differences in temperament; and a long history of cultural experiences and intuitions that affect moral choice and decision making (Haidt & Kesebir, 2010). *Moral identity* (refer back to page 489) also affects moral behavior (Hardy & Carlo, 2011). When moral goals are personally important, individuals are more likely to feel obligated to act on their moral judgments. In a study of low-SES African-American and Hispanic teenagers, those who emphasized moral traits and goals in their self-descriptions displayed exceptional levels of community service, but they did not differ from their agemates in moral reasoning (Hart & Fegley, 1995). That a synthesis of moral concern with sense of self can motivate moral action is also supported by a study of moral exemplars who have made outstanding contributions to such causes as civil rights, medical ethics, and religious freedom. Interview responses revealed that their most distinguishing characteristic is "seamless integration" of moral vision with personal identity (Colby & Damon, 1992, p. 309).

Researchers have begun to identify the origins of moral identity in hopes of capitalizing on it to promote moral commitment. As we saw earlier in this chapter, child-rearing practices—inductive discipline and clearly conveyed moral expectations—augment adolescents' moral identity. Strengthening moral self-perceptions at an early age may be a powerful way to increase the chances that moral cognitions are realized in behavior. In longitudinal research, firm conscience development (as measured by internalization of parents' rules) and empathic concern to mother's distress (a hurt finger) during the preschool years predicted strong moral self-perceptions at age 5, which—in turn—positively predicted children's competent, prosocial, rule-abiding behavior at age 6½ (Kochanska et al., 2010). Parenting strategies that launch conscience development and empathy on an early, favorable path may contribute vitally, in the long term, to moral identity and action.

Another possibility is that *just educational environments*—in which teachers guide students in democratic decision making and rule setting, resolving disputes civilly, and taking responsibility for others' welfare—enhance moral commitment (Atkins, Hart, & Donnelly, 2004). In one study, tenth graders who reported fair teacher treatment were more likely than those who had experienced unjust treatment (an unfair detention or a lower grade than they deserved) to regard excluding a peer on the basis of race as a moral transgression (Crystal, Killen, & Ruck, 2010). A compassionate and just school climate may be particularly important for poverty-stricken ethnic minority children and adolescents. For many such students, meaningful participation in their school community may be the crucial factor that prevents them from pessimistically concluding that prejudice and diminished opportunity are pervasive in society and, therefore, insurmountable (Hart & Atkins, 2002).

Schools can also expand students' opportunities to experience and explore moral emotions, thoughts, and actions by promoting civic engagement. As the Social Issues: Education box on page 508 reveals, encouraging civic responsibility in young people can help them see the connection between their personal interests and the public interest—an insight that may foster all aspects of morality.

Would you characterize your high school as a *just educational environment?* Cite specific features and experiences that may have contributed to students' moral development and civic engagement.

Religious Involvement and Moral Development

Recall that in resolving real-life moral dilemmas, many people express notions of religion and spirituality. For these individuals, morality and spirituality are inseparable; their moral values, judgments, and behaviors are deeply embedded in their faith.

Religion is especially important in U.S. family life. In recent national polls, nearly two-thirds of Americans reported actively practicing religion, compared with one-half of those in Canada, one-third of those in Great Britain and Italy, and even fewer elsewhere in Europe (CIA, 2009; Gallup News Service, 2006; Jones, 2003). People who are affiliated with a church, synagogue, or mosque and who regularly attend religious services include many parents with children. By middle childhood, children have begun to formulate religious and spiritual ideas that are remarkably complex and that serve as moral forces in their lives.

National survey findings reveal that 81 percent of U.S. teenagers identify with one religion, and an additional 3 percent with two religions (Smith & Denton, 2005). During adolescence, formal religious involvement declines—among U.S. youths, from 55 percent at ages 13 to 15 to 40 percent at ages 17 to 18 (Donahue & Benson, 1995; Kerestes & Youniss, 2003). The drop coincides with increased autonomy and efforts to construct a personally meaningful religious identity—a task usually not complete until the late teens or twenties (Hunsberger, Pratt, & Pancer, 2001).

These young choir members, who are part of a religious community, are likely to be advantaged in moral values and behavior compared with nonaffiliated peers.

But adolescents who remain part of a religious community are advantaged in moral values and behavior. Compared with nonaffiliated youths, they are more involved in community service activities aimed at helping the less fortunate (Kerestes, Youniss, & Metz, 2004). And religious involvement promotes responsible academic and social behavior and discourages misconduct (Dowling et al., 2004). It is associated with lower levels of drug and alcohol use, early sexual activity, and delinquency (Regnerus, Smith, & Fritsch, 2003).

A variety of factors probably contribute to these favorable outcomes. In a study of inner-city high school students, religiously involved adolescents were more likely to report trusting relationships with parents, adults, and friends who hold similar worldviews. The more activities they shared with this network, the higher they scored in empathic concern and prosocial behavior (King & Furrow, 2004). Furthermore, religious education and youth activities directly teach concern for others and provide opportunities for moral discussions and civic engagement. And adolescents who feel connected to a higher being may develop

SOCIAL ISSUES: EDUCATION

Development of Civic Responsibility

On Thanksgiving Day, Jill, Todd, and Brett joined their parents at a soup kitchen to serve a holiday dinner to poverty-stricken people. Throughout the year, Jill and Brett volunteered on Saturday mornings at a nursing home, conversing with bedridden elders. During a congressional election campaign, the three teenagers raised questions about issues at special youth meetings with candidates. At school, Todd and his girlfriend formed an organization devoted to promoting ethnic and racial tolerance.

These young people show a strong sense of *civic responsibility*—a complex combination of cognition, emotion, and behavior. Civic responsibility involves knowledge of political issues, a desire to make a difference in the community, and skills for achieving civic goals, such as how to resolve differing views fairly and conduct meetings so that all participants have a voice (Flanagan & Faison, 2001).

When young people engage in community service that exposes them to people in need or to public issues, they are especially likely to express a commitment to future service. And youth volunteers—who tend to be advanced in moral reasoning—gain further in moral maturity as a result of participating (Gibbs et al., 2007; Hart, Atkins, & Donnelly, 2006). Family, school, and community experiences contribute to adolescents' civic responsibility.

Family Influences

Teenagers whose parents encourage them to form opinions about controversial issues are more knowledgeable about civic issues and better able to see them from more than one perspective (Santoloupo & Pratt, 1994). Also, adolescents whose parents engage in community service and stress compassion tend to hold socially responsible values. When asked what causes unemployment or poverty, they more often mention situational and societal factors (lack of education, government policies, or the state of the economy) than individual factors (low intelligence or personal problems). Youths who endorse situational and societal causes, in turn, have more altruistic life goals, such as working to eradicate poverty or to preserve the earth for future generations (Flanagan & Tucker, 1999). And they engage in more civic activities into early adulthood (Zaff, Malanchuk, & Eccles, 2008).

School and Community Influences

A democratic climate at school in which teachers promote discussion of controversial issues while insisting that students listen to and respect one another, fosters knowledge and critical analysis of political concerns and commitment to social causes (Torney-Purta, Barber, & Wilkenfeld, 2007). Furthermore, high school students who view their community as one in which adults care about youths and work to make the community better report higher levels of civic participation (Kahne & Sporte, 2008). Participation in nonsport extracurricular activities at school and in youth organizations is also associated with civic commitment persisting into adulthood (Obradović & Masten, 2007).

© ECO IMAGES/GETTY IMAGES

For this young teenager in Los Angeles, planting a tree during an Earth Day celebration promotes a sense of civic responsibility—an effect that may persist into adulthood.

Two aspects of these involvements seem to account for their lasting impact. First, they introduce adolescents to the vision and skills required for mature civic engagement. Within student government, special-interest organizations, and other groups, young people see how their actions affect the wider school and community. They realize that collectively they can achieve results greater than any one person can achieve alone. And they learn to work together, balancing strong convictions with compromise (Atkins, Hart, & Donnelly, 2004; Kirshner, 2009). Second, while producing a weekly newspaper, participating in a dramatic production, or implementing a service project, young people explore political and moral ideals. Often they redefine their identities to include a responsibility to combat others' misfortunes (Wheeler, 2002).

The power of family, school, and community to promote civic responsibility may lie in discussions, educational practices, and activities that jointly foster moral thought, emotion, and behavior. In a comparison of nationally representative samples of 14-year-olds in 28 nations, U.S. young people excelled at community service, with 50 percent reporting membership in organizations devoted to volunteering (Torney-Purta, 2002).

Currently, 66 percent of U.S. public schools provide students with community service opportunities. Nearly half of these schools have *service-learning programs,* which integrate service activities into the academic curriculum, and about one-third of students enroll. High school students who are required to serve their communities express as strong a desire to remain engaged as do students who volunteer. And when they reach early adulthood, they are equally likely to vote and to participate in community organizations (Hart et al., 2007; Metz & Youniss, 2005).

Still, most U.S. schools offering service learning do not have policies encouraging or mandating such programs (Scales & Roehlkepartain, 2004). Furthermore, low-SES, inner-city youths—although they express high interest in social justice and contributing to society—score substantially lower than higher-SES youths in civic knowledge and participation (Balsano, 2005). A broad societal commitment to fostering civic character must pay special attention to supportive school and community experiences for these young people, so their eagerness to make a difference can be realized.

certain inner strengths, including prosocial values and a strong moral identity, that help them resolve real-life moral dilemmas maturely and translate their thinking into action (Hardy & Carlo, 2005; Sherrod & Spiewak, 2008).

Because most teenagers, regardless of formal affiliation, identify with a religious denomination and say they believe in a higher being, religious institutions may be uniquely suited to foster moral and prosocial commitments and discourage risky behaviors (Bridges & Moore, 2002). For youths in inner-city neighborhoods with few alternative sources of social support, outreach by religious institutions can lead to life-altering involvement (Jang & Johnson, 2001). An exception arises in religious cults, where rigid indoctrination into the group's beliefs, suppression of individuality, and estrangement from society all work against moral maturity (Richmond, 2004).

Further Challenges to Kohlberg's Theory

Although much support exists for Kohlberg's theory, it continues to face challenges. The most important of these concern Kohlberg's conception of moral maturity, the applicability of his stage model to moral reasoning and behavior in everyday life, and the appropriateness of his stages for characterizing children's moral reasoning.

A key controversy has to do with Kohlberg's belief that moral maturity is not achieved until the postconventional level. Yet if people had to reach Stages 5 and 6 to be truly morally mature, few individuals anywhere would measure up! John Gibbs (1991, 2010) argues that "postconventional morality" should not be viewed as the standard of maturity against which other levels are judged. Gibbs finds maturity in a revised understanding of Stages 3 and 4 that emphasizes ideal reciprocity. These stages are not "conventional," or based on social conformity, as Kohlberg assumed. Instead, they require profound moral constructions—an understanding of ideal reciprocity as the basis for relationships between people (Stage 3) and for widely accepted moral standards, set forth in rules and laws (Stage 4).

According to Gibbs (2010), "postconventional" moral reasoning is part of a highly reflective, metacognitive endeavor in which people grapple with existential issues: What is the meaning of life? Why be moral? Most people who contemplate such questions have attained advanced education, usually in philosophy—which sheds light on why Stages 5 and 6 are so rare. Occasionally, however, as a result of soul-searching life crises, life-threatening events, or spiritual awakenings, adolescents and adults without formal training in philosophy generate ethical insights into the meaning of existence—transformations that may heighten their resolve to lead a moral life. As a result, Gibbs notes, "postconventional" moral judgment is sometimes seen as early as adolescence, when young people first become capable of the formal operational and perspective-taking capacities needed to engage in it.

A more radical challenge comes from Dennis Krebs and Kathy Denton (2005), who claim that Kohlberg's theory inadequately accounts for morality in everyday life. Pointing to wide variability in maturity of moral reasoning across situations, these researchers favor abandoning Kohlberg's stages for a *pragmatic approach to morality.* They assert that each person makes moral judgments at varying levels of maturity, depending on the individual's current context and motivations: Conflict over a business deal is likely to evoke Stage 2 (instrumental purpose) reasoning, a friendship or marital dispute Stage 3 (ideal reciprocity) reasoning, and a breach of contract Stage 4 (social-order-maintaining) reasoning (Krebs et al., 1991). According to Krebs and Denton, everyday moral judgments—rather than being efforts to arrive at just solutions—are practical tools that people use to achieve their goals. To benefit personally, they often must advocate cooperation with others. But many people act first and then invoke moral judgments to rationalize their actions, regardless of whether the behavior is self-centered or altruistic (Haidt, 2001; Haidt & Kesebir, 2010). And sometimes people use moral judgments for immoral purposes—for example, to excuse their transgressions, blame others, or attract unmerited admiration. This pragmatism of moral reasoning, Krebs and Denton argue, is responsible for the lack of a strong association between moral judgment maturity and behavior.

Do people strive to resolve moral dilemmas in the fairest way possible, using the most advanced reasoning of which they are capable, only when presented with hypothetical dilemmas or real-life conflicts in which they are not personally involved? Gibbs (2006) points out that despite their mixed motives in everyday situations, people often rise above self-gratification to support others' rights. For example, moral exemplars in business—rather than yielding to Stage 2 reasoning—endorse the importance of trust, integrity, good faith, and just laws and codes of conduct (Damon, 2004). Furthermore, the pragmatic approach fails to recognize people's awareness of the greater adequacy of higher-stage moral judgments, which some individuals act on despite highly corrupt environments. And people who engage in sudden altruistic action may have previously considered the relevant moral issues so thoroughly that their cognitive structures activate automatically, inducing an immediate response (Gibbs et al., 2009a; Pizarro & Bloom, 2003). In these instances, individuals who appear to be engaging in after-the-fact rationalization are actually behaving with great forethought.

Finally, Kohlberg's stages tell us much more about moral understanding in adolescence and adulthood than in early and middle childhood. Nancy Eisenberg created dilemmas relevant to children's everyday lives that pit satisfying one's own desires against acting prosocially—for example, going to a birthday party versus taking time to help an injured peer and missing the party as a result (Eisenberg, 1986; Eisenberg et al., 1991, 1995). She found that children's *prosocial moral reasoning* is more advanced than Kohlberg's stages suggest. Furthermore, empathic perspective taking strengthens prosocial moral thought and its realization in everyday behavior (Eisenberg, Fabes, & Spinrad, 2006; Eisenberg, Zhoe, & Koller, 2001).

In sum, because Kohlberg focused on young children's tendency to center on prominent external features in their social world, he underestimated their potential for deeper moral understanding. In the following sections, we consider additional evidence on both child and adolescent moral reasoning.

The Domain Approach to Moral Understanding

Researchers taking a *domain approach to moral understanding* focus on children's developing capacity to distinguish and coordinate **moral imperatives,** which protect people's rights and welfare, from two other types of social rules and expectations: **social conventions,** customs determined solely by consensus, such as table manners and rituals of social interaction (saying "hello," "please," "thank you"); and **matters of personal choice,** such as friends, hairstyle, and leisure activities, which do not violate rights and are up to the individual (Killen, Margie, & Sinno, 2006; Nucci, 1996; Smetana, 2006). According to domain theorists, children construct these systems of social knowledge out of their experiences with three types of regularities in their social world (Turiel, 2006). And research reveals that children arrive at these distinctions early, displaying more advanced moral reasoning than assumed by the externally controlled vision of Kohlberg's preconventional morality.

Moral versus Social-Conventional Distinctions

Interviews with 3- and 4-year-olds reveal that they judge moral violations (unprovoked hitting, stealing an apple) as more wrong than violations of social conventions (eating ice cream with your fingers). They also say that moral violations would be wrong regardless of the setting—for example, in another country or school. And they indicate that moral (but not social-conventional) transgressions would be wrong even if an authority figure did not see them and no rules existed to prohibit them (Smetana, 2006; Yan & Smetana, 2003).

How do young children arrive at these distinctions? According to Elliott Turiel (2006), they do so by reflecting on their everyday social relations. They observe that after a moral offense, peers respond with strong negative emotion, describe their own injury or loss, tell another child to stop, or retaliate (Arsenio & Fleiss, 1996). And an adult who intervenes is likely to call attention to the victim's rights and feelings. Violations of social convention elicit less intense peer reactions. And in these situations, adults usually demand obedience without explanation or point to the importance of keeping order.

But while realizing that moral transgressions are worse than social-conventional violations, preschool and young school-age children (as Piaget pointed out) tend to reason rigidly and superficially *within* the moral domain, making judgments based on salient features and consequences while neglecting other important information. They claim that stealing and lying are always wrong, even when a person has a morally sound reason for doing so (Lourenco, 2003). Their explanations for why hitting others is wrong, even in the absence of rules against hitting, are simplistic and centered on physical harm—for example, "When you get hit, it hurts, and you start to cry" (Nucci, 2008). And their focus on outcomes means that they fail to realize that a promise is still a promise, even if it is unfulfilled (Maas, 2008; Maas & Abbeduto, 2001).

As they construct a flexible appreciation of moral rules, children clarify and link moral imperatives and social conventions. Gradually their understanding becomes more complex, taking into account an increasing number of variables, including the purpose of the rule; people's intentions, knowledge, and beliefs; and the context of people's behavior. School-age children, for example, distinguish social conventions with a clear *purpose* (not running in school hallways to prevent injuries) from ones with no obvious justification (crossing a "forbidden" line on the playground). They regard violations of purposeful conventions as closer to moral transgressions (Buchanan-Barrow & Barrett, 1998).

© SPENCER GRANT/GETTY IMAGES/PHOTOLIBRARY

Wearing a short, tight dress is a matter of personal choice to this teenager. But as her mother may point out, wearing the dress to a religious service would violate social conventions and potentially offend other congregants, yielding moral implications.

With age, children also realize that people's *intentions* and the *context* of their actions affect the moral implications of violating a social convention. In a Canadian study, many 6-year-olds always disapproved of flag burning, citing its physical consequences. But 8- to 10-year-olds made subtle distinctions, stating that because of a flag's symbolic value, burning it to express disapproval of a country or to start a cooking fire is worse than burning it accidentally. They also stated that public flag burning is worse than private flag burning because it inflicts emotional harm on others. But they recognized that burning a flag is a form of freedom of expression, and most agreed that it would be acceptable in a country that treated its citizens unfairly (Helwig & Prencipe, 1999).

In addition, school-age children appreciate that people whose *knowledge* differs may not be equally responsible for moral transgressions. Many 7-year-olds tolerate a teacher's decision to give more snacks to girls than to boys because she thinks (incorrectly) that girls need more food. But when a teacher gives girls more snacks because she holds an *immoral belief* ("It's all right to be nicer to girls than boys"), almost all children judge her actions negatively (Wainryb & Ford, 1998).

Relation of Personal and Moral Domains

Preschoolers display a budding awareness of the personal domain, conveyed through such statements as, "I'm gonna wear *this* shirt." As children's grasp of moral imperatives and social conventions strengthens, so does their conviction that certain choices are up to the individual. Early on, children learn that parents and teachers are willing to compromise on personal issues and, at times, on social-conventional matters but not on moral concerns.

Likewise, when children and adolescents challenge adult authority, they typically do so within the personal domain (Nucci, 2001, 2005). In diverse Western and non-Western cultures, concern with matters of personal choice intensifies during the teenage years—a reflection of adolescents' quest for identity and increasing independence (Neff & Helwig, 2002; Nucci, 2002). As, young people increasingly insist that parents not encroach on the personal arena (dress, hairstyle, diary records, friendships), disputes over these issues occur more often. Teenagers whose parents frequently intrude into their personal affairs report greater psychological stress (Hasebe, Nucci, & Nucci, 2004). In contrast, adolescents typically say that parents have a right to tell them what to do in moral and social-conventional situations. And when these issues spark disagreements, teenagers seldom challenge parental authority (Smetana & Daddis, 2002).

Notions of personal choice, in turn, enhance children's moral understanding. As early as age 6, children view freedom of speech and religion as individual rights, even if laws exist that deny those rights (Helwig, 2006). And they regard laws that discriminate against individuals—for example, laws that deny certain people access to medical care or education—as wrong and worthy of violating (Helwig & Jasiobedzka, 2001). In justifying their responses, children appeal to personal privileges and, by the end of middle childhood, to democratic ideals, such as the importance of individual rights for maintaining a fair society.

At the same time, older school-age children place limits on individual choice, depending on circumstances. While they believe that nonacademic matters (such as where to go on field trips) are best decided democratically, they regard the academic curriculum as the province of teachers, based on teachers' superior ability to make such choices (Helwig & Kim, 1999).

As they enlarge the range of issues they regard as personal, adolescents think more intently about conflicts between personal choice and community obligation—whether, and under what conditions, it is permissible to restrict speech, religion, marriage, childbearing, group membership, and other individual rights (Helwig, 1995; Wainryb, 1997). Teenagers display more subtle thinking than school-age children on such issues. For example, when asked if it is OK to exclude a child from a friendship or peer group on the basis of race or gender, fourth graders usually say exclusion is always unfair. But by tenth grade, young people, though increasingly mindful of fairness, indicate that under certain conditions—in intimate relationships (friendship) and private contexts (at home or in a small club), and on the basis of gender more often than race—exclusion is OK (Killen et al., 2002, 2007; Rutland, Killen, & Abrams, 2010). In explaining, they mention the right to personal choice as well as concerns about effective group functioning. Justifying her belief that members of an all-boys music club need not let a girl in, one tenth grader said, "It's not nice . . . but it's their club." Another commented, "[The girls and the boys] probably wouldn't relate on very many things" (Killen et al., 2002, p. 62).

As adolescents integrate personal rights with ideal reciprocity, they demand that the protections they want for themselves extend to others. For example, with age, they are more likely to defend the government's right to limit individual freedom to engage in risky health behaviors, such as smoking and drinking, in the interest of the larger public good (Flanagan, Stout, & Gallay, 2008). Similarly, they are increasingly mindful of the overlap among moral imperatives, social conventions, and personal choice. Eventually they realize that violating strongly held conventions in favor of asserting personal choices—showing up at a wedding in a T-shirt, talking out of turn at a student council meeting—can harm others, either by inducing distress or by undermining fair treatment. Over time, as their grasp of fairness deepens, young people realize that many social conventions have moral implications: They are vital for maintaining a just and peaceful society (Nucci, 2001). Notice how this understanding is central to Kohlberg's Stage 4, which is typically attained as adolescence draws to a close.

Culture and Moral, Social-Conventional, and Personal Distinctions

Children and adolescents in diverse Western and non-Western cultures use similar criteria to reason about moral, social-conventional, and personal concerns (Neff & Helwig, 2002; Nucci, 2002, 2005). For example, Chinese and Japanese young people, whose cultures place a high value on respect for authority, nevertheless say that adults have no right to interfere in their personal matters, such as how they spend their free time (Hasebe, Nucci, & Nucci, 2004; Helwig et al., 2003). A Colombian child illustrated this vehement defense of the right to personal control when asked if a teacher had the right to tell a student where to sit during circle time. In the absence of a moral reason from the teacher, the child emphatically declared, "She should be able to sit wherever she wants" (Ardila-Rey & Killen, 2001, p. 249).

Still, certain behaviors are classified differently across cultures. For example, East Indian Hindu children believe it is morally wrong to eat chicken the day after a father's death because, according to Hindu religious teachings, this will prevent the father's soul from reaching salvation. To American children, in contrast, this practice is an arbitrary convention

Milestones

Internalization of Moral Norms and Development of Moral Understanding

AGE	INTERNALIZATION OF MORAL NORMS	MORAL UNDERSTANDING
2–5 years	• Models many morally relevant behaviors • Responds with empathy-based guilt to transgressions 	• Tends to focus on salient features and consequences in moral judgment, such as physical damage, getting punished, or an adult's power or status • Begins to show sensitivity to others' intentions in moral judgment • At the end of this period, has a differentiated understanding of authority figures' legitimacy • Distinguishes moral imperatives, social conventions, and matters of personal choice
6–11 years	• Internalizes many norms of good conduct, including prosocial standards 	• Continues to emphasize superficial factors, including physical consequences and self-interest, in responses to moral dilemmas (Piaget's "heteronomous" and Kohlberg's preconventional Stages 1 and 2 morality) • Gradually understands ideal reciprocity and increasingly emphasizes people's intentions and expectations in moral judgment (Piaget's morality of cooperation and Kohlberg's "conventional" Stage 3 morality) • Clarifies and coordinates moral imperatives, social conventions, and matters of personal choice and, in judging violations, considers more variables—purpose of the rule, people's intentions, and context
12 years–adulthood		• Increasingly emphasizes ideal reciprocity as the basis for interpersonal relationships and societal laws (Kohlberg's "conventional" Stages 3 and 4 morality) • Becomes increasingly aware of the moral implications of social conventions and matters of personal choice • Highly reflective moral judgments that grapple with existential issues appear among a few individuals, usually with advanced education (Kohlberg's "postconventional" Stages 5 and 6) • Relationship between moral reasoning and behavior strengthens

Note: These milestones represent overall age trends. Individual differences exist in the precise age at which each milestone is attained.

(Shweder, Mahapatra, & Miller, 1990). But when children are asked about acts that obviously lead to harm or violate rights—breaking promises, destroying another's property, or kicking harmless animals—cross-cultural similarity prevails (Turiel, 2006). We are reminded, once again, that justice considerations are a universal feature of moral thought.

The research reviewed in the preceding sections reveals the richness and diversity of children's moral understanding. To fully represent the development of moral thought, researchers must examine children's responses to a wide range of problems. Consult the Milestones table above to review changes in moral internalization and construction during childhood and adolescence.

ASK YOURSELF

Review ■ How do recursive thought and understanding of ideal reciprocity contribute to moral development? Why are Kohlberg's Stages 3 and 4 morally mature constructions?

Connect ■ Do adolescents' efforts to resolve conflicts between personal choice and moral imperatives reflect their increasingly profound grasp of justice? Explain, citing examples.

Apply ■ Tam grew up in a small village culture, Lydia in a large industrial city. At age 15, Tam reasons at Kohlberg's Stage 3, Lydia at Stage 4. What factors probably account for the difference?

Reflect ■ Do you favor a cognitive-developmental or a pragmatic approach to morality, or both? What research evidence and personal experiences influenced your viewpoint?

▶ Discuss the development of morally relevant self-control, noting implications of individual differences for cognitive and social competencies.

Development of Morally Relevant Self-Control

The study of moral judgment tells us what people think they should do, and why, when faced with a moral problem. But people's good intentions often fall short. Whether children and adults act in accord with their beliefs depends in part on characteristics we call willpower, firm resolve, or, more simply, self-control. In Chapter 10, we considered individual differences in the broad temperamental dimension of *effortful control*—the extent to which children can manage their reactivity. Here we focus specifically on self-control in the moral domain: inhibiting urges to act in ways that violate moral standards, sometimes called *resistance to temptation.* Earlier in this book we noted that parental warmth, reasonable expectations and limit-setting, verbal guidance in managing emotion, inductive discipline, and modeling promote self-controlled behavior. But these practices become more effective when children acquire the ability to resist temptation. When and how does this capacity develop?

Toddlerhood

The beginnings of self-control are supported by achievements of the second year, discussed in earlier chapters. To behave in a self-controlled fashion, children must have some ability to think of themselves as separate, autonomous beings who can direct their own actions. And they must have the representational, memory, and inhibitory skills to recall a caregiver's directive and apply it to their own behavior (Rothbart & Bates, 2006).

As these capacities emerge between 12 and 18 months, the first glimmerings of self-control appear in the form of **compliance.** Toddlers show clear awareness of caregivers' wishes and expectations and can obey simple requests and commands. But at first, self-control depends heavily on caregiver support. According to Vygotsky (1934/1986), children cannot guide their own behavior until they have integrated standards represented in adult–child dialogues into their own self-directed speech (see Chapter 6). Compliance quickly leads to toddlers' first consciencelike verbalizations—for example, correcting the self by saying, "No, can't" before touching a delicate object or jumping on the sofa.

Researchers often study self-control by giving children tasks that, like the situations just mentioned, require **delay of gratification**—waiting for an appropriate time and place to engage in a tempting act. Between ages 1½ and 3, children show an increasing capacity to wait before eating a treat, opening a present, or playing with a toy (Vaughn, Kopp, & Krakow, 1984). Children who are advanced in development of attention and language tend to be better at delaying gratification—findings that help explain why girls are typically more self-controlled than boys (Else-Quest et al., 2006).

Like effortful control in general, young children's capacity to delay gratification is influenced by both biologically based temperament and quality of caregiving (Kochanska & Aksan, 2006; Kochanska & Knaack, 2003). Inhibited children find it easier to wait than angry, irritable children do. But toddlers who experience parental warmth and simple (as opposed to lengthy, detailed) statements that patiently redirect their behavior are more likely to be cooperative and resist temptation (Blandon & Volling, 2008; Hakman & Sullivan, 2009). Such parenting—which encourages and models patient, nonimpulsive behavior—is particularly important for temperamentally reactive children (refer to pages 426–427 in Chapter 10 to review these findings). As self-control improves, parents gradually increase the range of rules they expect toddlers to follow, from safety and respect for property and people to family routines, manners, and simple chores (Gralinski & Kopp, 1993).

Childhood and Adolescence

Although the capacity for self-control is in place by the third year, it is not complete. Cognitive development—in particular, gains in attention and mental representation—enables children to use a variety of effective self-instructional strategies. As a result, resistance to temptation improves.

Strategies for Resisting Temptation Walter Mischel has studied what children think and say to themselves that promotes resistance to temptation. In several studies, preschoolers were shown two rewards: a highly desirable one (10 mini-marshmallows) that they would have to wait for and a less desirable one (2 mini-marshmallows) that they could have right away (Mischel, 1996; Mischel & Ayduck, 2004). With age, performance improved (Atance & Jackson, 2009; Mischel, Shoda, & Rodriguez, 1989). At the same time, wide individual differences emerged: The most self-controlled preschoolers used any technique they could to divert their attention from the desired objects: covering their eyes, singing, even trying to sleep!

© JOSÉ LUIS PELAEZ/GETTY IMAGES/ICONICA

How will this 4-year-old resist temptation? If he diverts his attention by engaging in another activity or by imagining the strawberries to be inedible objects, he will be able to wait longer.

In everyday situations, preschoolers find it difficult to keep their minds off tempting activities and objects for long. When their thoughts turn to a prohibited goal, the way they mentally represent it has much to do with their success at self-control. Teaching preschoolers to transform the stimulus in ways that de-emphasize its arousing qualities—an approach that helps children shift attention and inhibit emotional reactivity—promotes delay of gratification. In one study, preschoolers who were told to think about marshmallows as "white and puffy clouds" waited much longer before eating a marshmallow reward than those who focused on marshmallows' "sweet and chewy properties" (Mischel & Baker, 1975).

Having something interesting to do while waiting also helps preschoolers divert attention from rewards and resist temptation (see earlier suggestions for reducing opportunities for misbehavior on page 495). In a modified delay-of-gratification task in which 3- to 5-year-olds could engage in enjoyable work (feeding marbles to a colorfully decorated, "hungry" Baby Bird), the amount of time children waited for a nearby, attractive reward more than doubled over simply waiting passively. But when the work was unappealing (sorting marbles), preschoolers were less successful (Peake, Hebl, & Mischel, 2002). They often looked up from the boring task, which increased the likelihood that the enticing reward would capture their attention.

During the school years, children become better at devising their own strategies for resisting temptation. By this time, self-control has become a flexible capacity for **moral self-regulation**—the ability to monitor one's own conduct, constantly adjusting it as circumstances present opportunities to violate inner standards (Kopp & Wyer, 1994; Thompson, Meyer, & McGinley, 2006).

Knowledge of Strategies Recall from Chapter 7 that metacognitive knowledge, or awareness of strategies, contributes to self-regulation. When asked about situational conditions and self-instructions likely to help delay gratification, school-age children suggested a broader array of arousal-reducing strategies with age. But not until the late elementary school years did they mention techniques involving transformations of rewards or their own

LOOK and LISTEN

Propose a situation involving waiting for a larger, delayed reward in lieu of taking an immediate, lesser reward to two or three school-age children. Ask what each child would do to delay gratification. Are the strategies children generate consistent with research findings?

arousal states. For example, one 11-year-old proposed saying, "The marshmallows are filled with an evil spell." Another said he would tell himself, "I hate marshmallows; I can't stand them. But when the grown-up gets back, I'll tell myself 'I love marshmallows' and eat it" (Mischel & Mischel, 1983, p. 609). Once this transforming ideation appears, it greatly facilitates moral self-regulation (Rodriguez, Mischel, & Shoda, 1989).

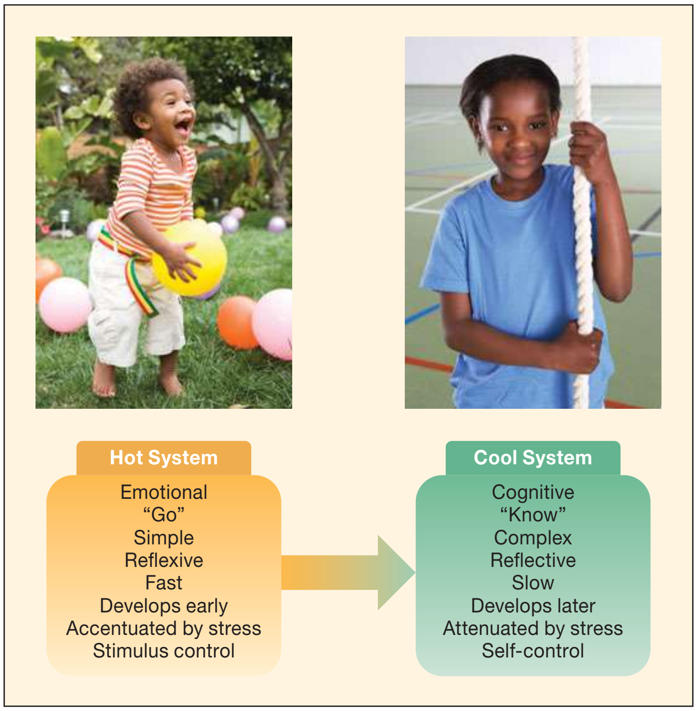

FIGURE 12.4 Characteristics of "hot" and "cool" processing systems in the development of self-control. With age, the cognitive, reflective cool system gains control over emotional, reactive hot system. **TAKE A MOMENT...** Return to Table 10.1 on page 420 in Chapter 10 to review Rothbart's reactive and self-regulatory dimensions of temperament. How are they similar to the hot and cool processing systems depicted here? (Adapted from Kross & Mischel, 2010.)

Individual Differences

In a series of studies, 4-year-olds who were better at delaying gratification were especially adept as adolescents in applying metacognitive skills to their behavior and in inhibiting impulsive responding. In addition, their parents saw them as more responsive to reason, as better at concentrating and planning ahead, and as coping with stress more maturely. When applying to college, those who had been self-controlled preschoolers scored higher on the Scholastic Assessment Test (SAT), although they were no more intelligent than other individuals (Eigsti et al. 2006; Mischel, Shoda, & Peake, 1988; Shoda, Mischel, & Peake, 1990). Furthermore, children who are better at delaying gratification can wait long enough to interpret social cues accurately, which supports effective social problem solving and positive peer relations (Gronau & Waas, 1997).

Mischel proposes that the interaction of two processing systems—*hot* and *cool*—governs the development of self-control and accounts for individual differences (Kross & Mischel, 2010; Mischel & Ayduk, 2004). Figure 12.4 depicts the characteristics of each. With age, the emotional, reactive hot system is increasingly subordinated to the cognitive, reflective cool system, as a result of improved functioning of the prefrontal cortex, which is centrally involved in executive function (see page 281 in Chapter 7).

Throughout childhood and adolescence, temperament and parenting jointly influence the extent to which cool-system representations gain control over hot-system reactivity. **TAKE A MOMENT...** Describe evidence from this and previous chapters indicating that power-assertive, inconsistent discipline—especially with temperamentally vulnerable children—results in a poorly functioning cool system, enabling the hot system to prevail. Such children display hostile, unruly behavior and serious deficits in moral conduct. Refer to the Milestones table on the following page for a summary of changes in self-control as well as in aggression—our next topic.

- Discuss the development of aggression, noting various influences, and describe successful interventions.

The Other Side of Self-Control: Development of Aggression

Beginning in late infancy, all children display aggression from time to time. As opportunities to interact with siblings and peers increase, aggressive outbursts occur more often (Dodge, Coie, & Lynam, 2006; Tremblay, 2004). Although at times aggression serves prosocial ends (for example, stopping a victimizer from harming others), most human aggressive acts are clearly antisocial.

As early as the preschool years, some children show abnormally high rates of hostility, assaulting others verbally and physically with little or no provocation. If allowed to continue,

Milestones

Development of Morally Relevant Self-Control and Aggression

AGE	SELF-CONTROL	AGGRESSION
1½ –5 years	• Compliance and delay of gratification emerge and improve. • Benefits from adult-provided strategies for delaying gratification.	• Proactive, or instrumental, aggression declines, while reactive (hostile aggression) increases. • Physical aggression declines, while verbal aggression increases. • Relational aggression appears.
6–11 years	• Generates an increasing variety of strategies for delaying gratification. • Displays a flexible capacity for moral self-regulation.	• Reactive, or hostile, aggression (largely verbal and relational) continues to increase. • Girls' relational aggression becomes increasingly indirect.
12–20 years	• Continues to gain in moral self-regulation.	• Teacher- and peer-reported aggression declines. • Delinquency rises, then declines.

Note: These milestones represent overall age trends. Individual differences exist in the precise age at which each milestone is attained.

their belligerent behavior can lead to lasting delays in moral development, deficits in self-control, and ultimately an antisocial lifestyle. To understand this process, let's see how aggression develops during childhood and adolescence.

Emergence of Aggression

In the second half of the first year, infants develop the cognitive capacity to identify sources of anger and frustration and the motor skills to lash out at them (see Chapter 10). By the second year, aggressive acts with two distinct purposes emerge. Initially, the most common is **proactive** (or *instrumental*) **aggression,** in which children act to fulfill a need or desire—obtain an object, privilege, space, or social reward, such as adult attention or (in older children) peer admiration—and unemotionally attack a person to achieve their goal. The other type, **reactive** (or *hostile*) **aggression,** is an angry, defensive response to a provocation or a blocked goal and is meant to hurt another person (Dodge, Coie, & Lynam, 2006; Little et al., 2003).

Naturalistic observations of children in classrooms or at play reveal low positive correlations between proactive and reactive aggression (Polman et al., 2007). But when aggression is assessed using parent or teacher reports, proactive and reactive aggression are strongly correlated (Vitaro, Brendgen, & Tremblay, 2002). Thus, the extent to which the two types of aggression represent distinct styles is unclear. At least some, and perhaps many, aggressive children engage in both, and most studies do not distinguish between them.

Proactive and reactive aggression come in three forms, which are the focus of the majority of research:

- **Physical aggression** harms others through physical injury—pushing, hitting, kicking, or punching others, or destroying another's property.

- **Verbal aggression** harms others through threats of physical aggression, name-calling, or hostile teasing.
- **Relational aggression** damages another's peer relationships through social exclusion, malicious gossip, or friendship manipulation.

Although verbal aggression is always direct, physical and relational aggression can be either *direct* or *indirect.* For example, hitting injures a person directly, whereas destroying property indirectly inflicts physical harm. Similarly, saying, "Do what I say, or I won't be your friend," conveys relational aggression directly, while spreading rumors, refusing to talk to a peer, or manipulating friendships by saying behind someone's back, "Don't play with her; she's a nerd," does so indirectly.

Although physical aggression largely gives way to verbal aggression during early and middle childhood, gender differences remain. Boys are more physically aggressive than girls.

Aggression in Early and Middle Childhood

Between ages 3 and 6, physical aggression decreases, whereas verbal aggression increases (Alink et al., 2006; Tremblay et al., 1999). Rapid language development contributes to this change, but it is also due to adults' and peers' strong negative reactions to physical attacks. Furthermore, proactive aggression declines as preschoolers' improved capacity to delay gratification enables them to resist grabbing others' possessions. But reactive aggression in verbal and relational forms tends to rise over early and middle childhood (Côté et al., 2007; Tremblay, 2000). Older children are better able to detect malicious intentions and, as a result, more often respond in hostile ways.

By age 17 months, boys are considerably more physically aggressive than girls—a difference found throughout childhood in many cultures (Baillargeon et al., 2007; Card et al., 2008; Dodge, Coie, & Lynam, 2006). As we will see in Chapter 13, when we consider sex differences in aggression in greater detail, biological factors—in particular, the effects of male sex hormones (androgens) and temperamental traits on which boys and girls differ—contribute to the early greater prevalence of physical attacks by boys. Gender-role conformity is also a factor. As soon as 2-year-olds become dimly aware of gender stereotypes—that males and females are expected to behave differently—physical aggression drops off more sharply for girls than for boys (Fagot & Leinbach, 1989).

Although girls have a reputation for being verbally and relationally more aggressive than boys, Chapter 13 will reveal that the sex difference is small (Crick et al., 2004, 2006; Crick, Ostrov, & Werner, 2006). Beginning in the preschool years, girls concentrate most of their aggressive acts in the relational category. Boys inflict harm in more variable ways and, therefore, display overall rates of aggression that are much higher than girls'.

At the same time, girls more often use indirect relational tactics that—in disrupting intimate bonds especially important to girls—can be particularly mean. Whereas physical attacks are usually brief, acts of indirect relational aggression may extend for hours, weeks, or even months (Nelson, Robinson, & Hart, 2005; Underwood, 2003). In one instance, a second-grade girl formed a "pretty-girls club" at school and—for nearly an entire school year—convinced its members to exclude several classmates by saying they were "ugly and smelly." At least in childhood, then, it may not be meaningful to describe one sex as more aggressive than the other.

Aggression and Delinquency in Adolescence

Although most young people decline in teacher- and peer-reported aggression in adolescence, the teenage years are accompanied by a rise in delinquent acts. Although U.S. youth crime has declined since the mid-1990s, 12- to 17-year-olds account for a substantial proportion of police arrests—14, although they constitute only 8 percent of the population (U.S. Department of Justice, 2010). When asked directly and confidentially about lawbreaking, almost all teenagers admit to having committed some sort of offense—usually a minor crime, such as petty stealing or disorderly conduct (Flannery et al., 2003).

Both police arrests and self-reports show that delinquency rises over early and middle adolescence and then declines (Farrington, 2009; U.S. Department of Justice, 2010). Recall from Chapter 5 that changes in the brain's emotional/social network at puberty contribute to an increase in antisocial behavior among teenagers (see pages 190–191). Over time, decision making, emotional self-regulation, and moral reasoning improve; peers become less influential; and young people enter social contexts (such as higher education, work, career, and marriage) that are less conducive to lawbreaking.

For most adolescents, a brush with the law does not forecast long-term antisocial behavior. But repeated arrests are cause for concern. Teenagers are responsible for 15 percent of violent crimes in the United States (U.S. Department of Justice, 2010). A small percentage become recurrent offenders, who commit most of these crimes, and some enter a life of crime.

In adolescence, the gender gap in physical aggression widens (Chesney-Lind, 2001). Although girls account for about one in five adolescent arrests for violence, their offenses are largely limited to simple assault (such as pushing and spitting), the least serious category. Once labeled status offenses (noncriminal behavior), today these acts are more likely to lead to arrests, especially in physical exchanges with parents, who may report the youth's behavior to the police (Chesney-Lind & Belknap, 2004). Serious violent crime, however, continues to be mostly the domain of boys (Dahlberg & Simon, 2006).

SES and ethnicity are strong predictors of arrests but only mildly related to teenagers' self-reports of antisocial acts. The difference is due to the tendency to arrest, charge, and punish low-SES ethnic minority youths more often than their higher-SES white and Asian counterparts (Farrington, 2009; U.S. Department of Justice, 2010). In isolation from other life circumstances, ethnicity tells us little about youths' propensity to engage in violence and other lawbreaking acts.

© CHROMORANGE/PICTURE-ALLIANCE/NEWSCOM

Delinquency—usually petty stealing and disorderly conduct—rises in early adolescence and then declines. But a small percentage of young people engage in repeated, serious offenses and are at risk for a life of crime.

Stability of Aggression

Children high in either physical or relational aggression relative to their agemates tend to remain so over time (Côté et al., 2007; Vaillancourt et al., 2003). Following more than 1,000 Canadian, New Zealand, and U.S. boys from ages 6 to 15, researchers identified four main patterns of change. Kindergarten boys high in physical aggression (4 percent of the sample) were especially likely to move to high-level adolescent aggression, becoming involved in violent delinquency. In contrast, kindergarten boys who were moderately physically aggressive usually declined in physical aggression over time. And boys who rarely physically aggressed in early childhood typically remained nonaggressive. However, a small number of boys high in oppositional behavior (such as disobedience and inconsiderateness) but not in physical aggression were prone to less violent forms of adolescent delinquency (such as theft) (Brame, Nagin, & Tremblay, 2001; Nagin & Tremblay, 1999).

In other longitudinal evidence, high physical aggression that diminished over the school years was often replaced with indirect relational aggression. Although the trend applied to both genders, girls displayed it more often than boys (Vaillancourt, Miller, & Boyle, 2009). These children seem to deploy their improved perspective-taking capacities antisocially—to perpetrate behind-the-scenes relational attacks. Their aggressiveness actually remains stable—just expressed in a different form. For both boys and girls, persistently high physical or relational aggression predicts later internalizing and externalizing

BIOLOGY and ENVIRONMENT

Two Routes to Adolescent Delinquency

Persistent adolescent delinquency follows two paths of development, one involving a small number of youths with an onset of conduct problems in childhood, the second a larger number with an onset in adolescence. The early-onset type is far more likely to lead to a life-course pattern of aggression and criminality (Moffitt, 2006b). The late-onset type usually does not persist beyond the transition to early adulthood.

Both childhood-onset and adolescent-onset youths engage in serious offenses; associate with deviant peers; participate in substance abuse, unsafe sex, and dangerous driving; and spend time in correctional facilities. Why does antisocial activity more often continue and escalate into violence in the first group? Longitudinal studies yield similar answers to this question. Most research has focused on boys, but several investigations report that girls who were physically aggressive in childhood are also at risk for later problems—occasionally violent delinquency but more often other norm-violating behaviors and psychological disorders (Broidy et al., 2003; Chamberlain, 2003). Early relational aggression is linked to adolescent conduct problems as well.

Early-Onset Type

Early-onset youngsters seem to inherit traits that predispose them to aggressiveness (Pettit, 2004). For example, violence-prone boys are emotionally negative, restless, willful, and physically aggressive as early as age 2. They also show subtle deficits in cognitive functioning that seem to contribute to disruptions in the development of language, memory, and cognitive and emotional self-regulation (Moffitt, 2006a; Shaw et al., 2003). Some have attention-deficit hyperactivity disorder (ADHD), which compounds their learning and self-control problems (see Chapter 7, pages 290–291).

Yet these biological risks are not sufficient to sustain antisocial behavior: Most early-onset boys decline in aggression over time. Among those who follow the life-course path, inept parenting transforms their undercontrolled style into defiance and persistent aggression—strong predictors of violent delinquency in adolescence (Brame, Nagin, & Tremblay, 2001; Broidy et al., 2003). As they fail academically and are rejected by peers, they befriend other deviant youths, who facilitate one another's violent behavior while relieving loneliness (see Figure 12.5) (Hughes, 2010; Lacourse et al., 2003). Limited cognitive and social skills result in high rates of school dropout and unemployment, contributing further to antisocial involvements. Often these boys experience their first arrest before age 14—a good indicator that they will be chronic offenders by age 18 (Patterson & Yoerger, 2002).

Preschoolers high in relational aggression also tend to be hyperactive and frequently in conflict with peers and adults (Willoughby, Kupersmidt, & Bryant, 2001). As these behaviors trigger peer rejection, relationally aggressive girls befriend other girls high in relational hostility, and their relational aggression rises (Werner & Crick, 2004). Adolescents high in relational aggression are often angry, vengeful, and defiant of adult rules. Among teenagers who combine physical and relational hostility, these oppositional reactions intensify, increasing the likelihood of serious antisocial activity (Harachi et al., 2006; Prinstein, Boergers, & Vernberg, 2001).

Late-Onset Type

Other youths first display antisocial behavior around the time of puberty, gradually increasing their involvement. Their conduct problems

difficulties and social skills deficits, including loneliness, anxiety, depression, poor-quality friendships, and antisocial activity (Campbell et al., 2006; Côté et al., 2007; Crick, Ostrov, & Werner, 2006).

As the Biology and Environment box above confirms, aggressive behavior that emerges in childhood and endures is far more likely to translate into long-term adjustment difficulties than aggression that first appears in adolescence. Although some children—especially those who are irritable, fearless, impulsive, and overactive—are at risk for aggression, whether or not they become aggressive largely depends on child-rearing conditions. Strife-ridden families, poor parenting practices, aggressive peers, and televised violence strongly predict both antisocial activity and reduced sensitivity to others' suffering. In this chapter, we focus on family and peer influences, reserving TV influences for Chapter 15. We will also see that community and cultural influences can heighten or reduce children's risk of sustaining a hostile interpersonal style.

The Family as Training Ground for Aggressive Behavior

The same parenting behaviors that undermine moral internalization and self-control—love withdrawal, power assertion, critical remarks, physical punishment, and inconsistent discipline—are linked to aggression from early childhood through adolescence in diverse cultures, with most of these practices predicting both physical and relational forms (Bradford et al., 2003; Casas et al., 2006; Côté et al., 2007; Gershoff et al., 2010; Kuppens et al., 2009; Nelson et al., 2006).

arise from typical adolescent novelty seeking and receptiveness to peer influence. For some, quality of parenting may decline for a time, perhaps as a result of family stresses or the challenges of disciplining an unruly teenager (Moffitt, 2006a). When age brings gratifying adult privileges, these youths draw on prosocial skills mastered before adolescence and abandon their antisocial ways.

A few late-onset youths do continue to engage in antisocial acts. The seriousness of their adolescent offenses seems to trap them in situations that close off opportunities for responsible behavior. Being employed or in school and forming positive, close relationships predict an end to criminal offending by age 20 to 25 (Farrington, Ttofi, & Coid, 2009; Stouthamer-Loeber et al., 2004). In contrast, the longer antisocial young people spend in prison, the more likely they are to sustain a life of crime.

These findings suggest a need for a fresh look at policies aimed at stopping youth crime. Keeping youth offenders locked up for many years disrupts their vocational lives and access to social support during a crucial period of development, condemning them to a bleak future.

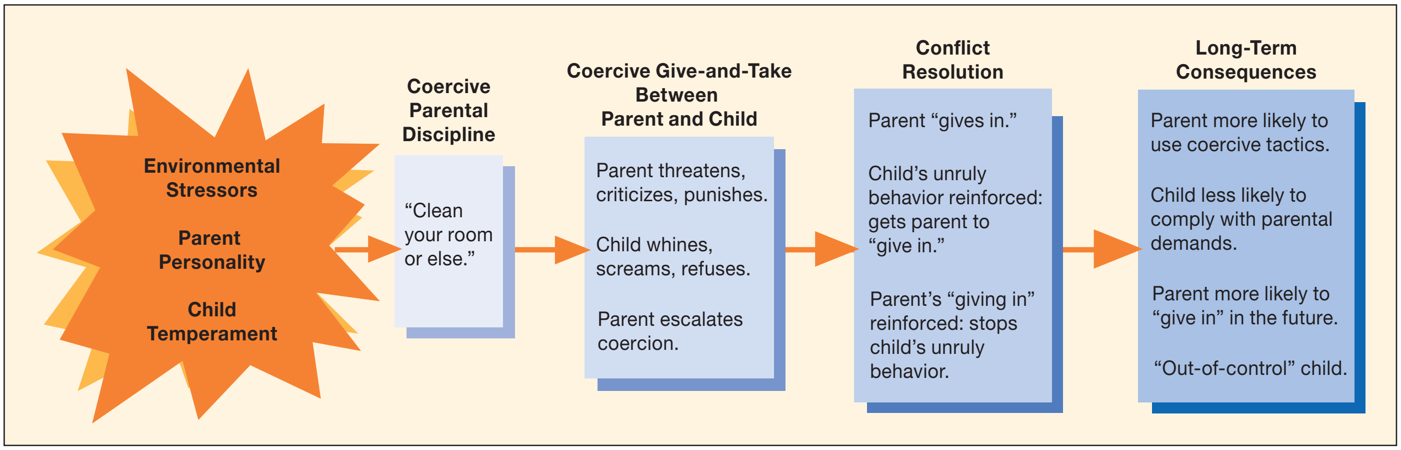
Commitment to deviant peer group
Delinquency

FIGURE 12.5 **Path to chronic delinquency for adolescents with childhood-onset antisocial behavior.** Difficult temperament and cognitive deficits characterize many of these youths in early childhood; some have attention-deficit hyperactivity disorder. Inept parenting transforms biologically based self-control difficulties into hostility and defiance.

Home observations of aggressive children reveal that anger and punitiveness quickly create a conflict-ridden family atmosphere and an "out-of-control" child. As Figure 12.6 on page 522 shows, the pattern begins with forceful discipline, which occurs more often with stressful life experiences (such as economic hardship or marital conflict), a parent with an unstable personality, or a temperamentally difficult child (Dodge, Coie, & Lynam, 2006). Typically, the parent threatens, criticizes, and punishes, and the child angrily resists until the parent gives in. At the end of each exchange, both parent and child get relief from stopping the other's unpleasant behavior, so the behaviors repeat and escalate.

As these cycles become more frequent, they generate anxiety and irritability among other family members, who soon join in the hostile interactions. Compared with siblings in typical families, preschool siblings who have critical, punitive parents are more aggressive toward one another. Physically, verbally, and relationally destructive sibling conflict, in turn, quickly spreads to peer relationships, contributing to poor impulse control and antisocial behavior by the early school years (Garcia et al., 2000; Ostrov, Crick, & Stauffacher, 2006).

Boys are more likely than girls to be targets of harsh, inconsistent discipline because they are more active and impulsive and therefore harder to control. When children who are extreme in these characteristics are exposed to emotionally negative, inept parenting, their capacity for emotional self-regulation, empathic responding, and guilt after transgressions is severely disrupted (Eisenberg, Eggum, & Edwards, 2010). Consequently, they lash out when disappointed, frustrated, or faced with a sad or fearful victim, and aggression persists (refer again to the Biology and Environment box).



Environmental Stressors
Parent Personality
Child Temperament
Coercive Parental Discipline
"Clean your room or else."
Coercive Give-and-Take Between Parent and Child
Parent threatens, criticizes, punishes.
Child whines, screams, refuses.
Parent escalates coercion.
Conflict Resolution
Parent "gives in."
Child's unruly behavior reinforced: gets parent to "give in."
Parent's "giving in" reinforced: stops child's unruly behavior.
Long-Term Consequences
Parent more likely to use coercive tactics.
Child less likely to comply with parental demands.
Parent more likely to "give in" in the future.
"Out-of-control" child.

FIGURE 12.6 **Coercive interaction pattern that promotes and sustains aggression between family members.**

Besides fostering aggression directly, parents can encourage it indirectly, through poor supervision of children (Vitaro, Brendgen, & Tremblay, 2000). Unfortunately, children from conflict-ridden homes who already display serious antisocial tendencies lack a cooperative parent–child relationship, which enables adequate parental monitoring. As a result, few if any limits are placed on out-of-home activities and association with antisocial friends, who encourage their hostile style of responding.

Social-Cognitive Deficits and Distortions

Children who are products of these family processes soon acquire a violent and callous view of the social world. Those who are high in reactive aggression often see hostile intent where it does not exist—in situations where peers' intentions are unclear, where harm is accidental, and even where peers are trying to be helpful (Lochman & Dodge, 1998; Orobio de Castro et al., 2002). When such children feel threatened (for example, a researcher tells them that a peer they will work with is in a bad mood and might pick a fight), they are especially likely to interpret accidental mishaps as hostile (Williams et al., 2003). As a result, they make many unprovoked attacks, which trigger aggressive retaliations.

Children high in proactive aggression have different social-cognitive deficits. Compared with their nonaggressive agemates, they believe there are more benefits and fewer costs for engaging in destructive acts (Arsenio, 2010; Dodge et al., 1997). And they are more likely to think that aggression "works," producing material rewards and reducing others' unpleasant behaviors (Arsenio & Lemerise, 2001; Goldstein & Tisak, 2004). Thus, they callously use aggression to advance their own goals and are relatively unconcerned about causing suffering in others—an aggressive style associated with later, more severe conduct problems, violent behavior, and delinquency (Marsee & Frick, 2010).

Another biased social-cognitive attribute of proactively aggressive children and youths is overly high self-esteem, even in the face of academic and social failings. When their arrogant, cocky behavior prompts others to challenge their inflated but vulnerable self-image, they lash out angrily (Costello & Dunaway, 2003; Orobio de Castro et al., 2007). Their narcissism is also associated with a sense of personal entitlement, lack of empathy, and sophisticated, highly manipulative relationally aggressive tactics aimed at gaining power over others (Barry, Frick, & Killian, 2003; Kerig & Stellwagen, 2010).

Furthermore, aggressive young people may neutralize their basic biological capacity for empathy by using such cognitive distortion techniques as blaming their victims. As a result, they retain a positive self-evaluation after behaving aggressively (Liau, Barriga, & Gibbs, 1998; McCrady et al., 2008). Looking back on his burglaries, one delinquent reflected, "If I started feeling bad, I'd say to myself, 'Tough rocks for him. He should have had his house locked better and the alarm on'" (Samenow, 1984, p. 115).

Antisocial adolescents are delayed in maturity of moral judgment, and they tend to view aggression as within the social conventional and personal domains rather than the moral domain (Harvey, Fletcher, & French, 2001; Tisak, Tisak, & Goldstein, 2006). In this way, they minimize the harmful impact of their antisocial acts, rationalizing their behavior as acceptable or even admirable. These youths also score low in moral identity. In a study of 16- to 19-year-olds, those whose moral reasoning was immature and who also judged moral values as personally unimportant were prone to self-serving cognitive distortions (such as blaming the victim or minimizing the harm done), which predicted high levels of aggressive behavior (Barriga et al., 2001). Compared with boys, girls scored higher in moral identity and lower cognitive distortions—likely contributors to their lower overall aggressiveness.

Community and Cultural Influences

In poverty-stricken neighborhoods with a wide range of stressors, including poor-quality schools, limited recreational and employment opportunities, and high adult criminality, youth antisocial behavior is more likely (Leventhal, Dupere, & Brooks-Gunn, 2009). Children and adolescents have easy access to deviant peers, drugs, and (in the United States) firearms, all of which are linked to violence. And teenagers are especially likely to be recruited into antisocial gangs, whose members commit the vast majority of violent delinquent acts (Thornberry & Krohn, 2001). Furthermore, schools in these locales typically fail to meet students' developmental needs (Chung, Mulvey, & Steinberg, 2011; Flannery et al., 2003). Large classes, weak instruction, rigid rules, and reduced academic expectations and opportunities are associated with higher rates of lawbreaking, even after other influences are controlled.

Furthermore, the community conditions just described heighten in young people a hostile view of people and relationships, a preference for immediate rewards, and a cynical attitude toward social conventions and moral norms (Simons & Burt, 2011). These social-cognitive biases, in addition to others noted in the previous section, increase the chances that adolescents will interpret situations in ways that legitimize antisocial behavior.

Ethnic and political prejudices further magnify the risk of angry, combative responses. In inner-city ghettos and in war-torn areas of the world, large numbers of children live in the midst of constant danger, chaos, and deprivation. As the Cultural Influences box on page 524 reveals, these youngsters are at risk for severe emotional stress, deficits in moral reasoning, and behavior problems.

Helping Children and Parents Control Aggression

Treatment for aggressive children must break the cycle of hostilities between family members and promote effective ways of relating to others. Interventions with preschool and school-age children have been most successful. Once antisocial patterns persist into adolescence, so many factors act to sustain them that treatment is far more difficult.

Parent Training Parent training programs based on social learning theory have been devised to improve the parenting of preschool and school-age children with conduct problems. In one highly effective approach called *Incredible Years,* parents complete 18 weekly group sessions facilitated by two professionals, who teach parenting techniques for promoting children's academic, emotional, and social skills and for managing disruptive behaviors. Sessions include coaching, modeling, and practicing effective parenting behaviors—experiences aimed at interrupting parent–child destructive interaction while promoting positive relationships and competencies (Webster-Stratton & Reid, 2010b). A special focus is positive parenting (see page 495), including giving children positive attention, encouragement, and praise for prosocial behaviors. The coercive cycles of parents and aggressive children are so pervasive that these children often are punished even when they do behave appropriately.

Incredible Years also offers a complementary six-day training program for teachers, directed at improving classroom management strategies and strengthening students' social

CULTURAL INFLUENCES

Impact of Ethnic and Political Violence on Children

AP IMAGES/ANJA NIEDRINGHAUS

A trauma counselor comforts a child amid the rubble of her neighborhood in the Gaza Strip. Many children of war lose their sense of safety. They need special support from caring adults to prevent lasting emotional problems.

Around the world, many children live with armed conflict, terrorism, and other acts of violence stemming from ethnic and political tensions. Some children may participate in fighting, either because they are forced or because they want to please adults. Others are kidnapped, assaulted, and tortured. Those who are bystanders often come under direct fire and may be killed or physically maimed. And many watch in horror as family members, friends, and neighbors flee, are wounded, or die. In the past decade, wars have left 6 million children physically disabled, 20 million homeless, and more than 1 million separated from parents (UNICEF, 2011).

When war and social crises are temporary, most children can be comforted and do not show long-term emotional difficulties. But chronic danger requires children to make substantial adjustments that can seriously impair their psychological functioning. Many children of war lose their sense of safety, become desensitized to violence, are haunted by terrifying intrusive memories, display immature moral reasoning, and build a pessimistic view of the future. Anxiety and depression increase, as do aggression and antisocial behavior (Eisenberg & Silver, 2011; Klingman, 2006). These outcomes appear to be culturally universal, appearing among children from every war zone studied—from Bosnia, Angola, Rwanda, and the Sudan to the West Bank, Gaza, Afghanistan, and Iraq (Barenbaum, Ruchkin, & Schwab-Stone, 2004).

Parental affection and reassurance are the best protection against lasting problems. When parents offer security, discuss traumatic experiences sympathetically, and serve as role models of calm emotional strength, most children can withstand even extreme war-related violence (Gewirtz, Forgatch, & Wieling, 2008). Children who are separated from parents must rely on help from their communities. Orphans in Eritrea who were placed in residential settings where they could form close emotional ties with an adult showed less emotional stress five years later than orphans placed in impersonal settings (Wolff & Fesseha, 1999). Education and recreation programs are powerful safeguards, too, providing children with consistency in their lives along with teacher and peer supports.

With the September 11, 2001, terrorist attacks on the World Trade Center and the Pentagon, some U.S. children experienced extreme wartime violence firsthand, watching through classroom windows as the planes struck and as the towers were engulfed in flames and crumbled. Most children, however, learned about the attacks indirectly—from the media or from caregivers or peers. Although both direct and indirect exposure triggered child and adolescent distress, extended exposure—having a family member affected or repeatedly witnessing the attacks on TV—resulted in more severe symptoms (Agronick et al., 2007; Otto et al., 2007; Rosen & Cohen, 2010). During the following months, distress reactions declined, though more slowly for children with conflict-ridden parent–child relationships or preexisting adjustment problems.

Unlike many war-traumatized children in the developing world, students in New York's Public School 31, who watched from their classrooms as the towers collapsed, received immediate intervention—a "trauma curriculum" in which they expressed their emotions through writing, drawing, and discussion and participated in experiences aimed at restoring trust and tolerance (Lagnado, 2001). Older students learned about the feelings of their Muslim classmates, the dire condition of children in Afghanistan, and ways to help victims as a means of overcoming a sense of helplessness.

When wartime drains families and communities of resources, international organizations must step in and help children. Efforts to preserve children's physical, psychological, and educational well-being may be the best way to stop transmission of violence to the next generation.

skills, friendships, and emotional self-regulation. And a complementary, 22-week program intervenes directly with children teaching appropriate classroom behavior, self-control, and social skills.

Evaluations in which families with aggressive children were randomly assigned to either Incredible Years or control groups reveal that the program is highly effective at improving parenting and reducing child behavior problems. Combining parent training with teacher and/or child intervention strengthens child outcomes (Webster-Stratton & Herman, 2010). And effects of parent training endure. In one 8- to 12-year-follow-up, 75 percent of young children with serious conduct problems whose parents participated in Incredible Years were well-adjusted as teenagers (Webster-Stratton & Reid, 2010a; Webster-Stratton, Rinaldi, & Reid, 2011). These favorable effects contrast sharply with the profound adjustment problems typically displayed by youths with early-onset conduct difficulties.

Social-Cognitive Interventions The social-cognitive deficits and distortions of aggressive children prevent them from empathizing with another person's pain and suffering. And because most aggressive children have few opportunities to witness family members acting in sensitive, caring ways, they miss early experiences that are vital for promoting empathy and sympathy (see Chapter 10). In such children, these responses may have to be directly taught.

School-based social-cognitive treatments focus on teaching children and adolescents to attend to relevant, nonhostile social cues, seek additional information before acting, generate effective social problem-solving strategies, and evaluate the likely effectiveness of potential responses. These interventions increase skill in solving social problems, decrease endorsement of beliefs supporting aggression, reduce hostile behaviors, and improve relationships with peers (see page 482 in Chapter 11). Training in perspective taking also helps by promoting more accurate interpretation of social cues, empathy, and sympathetic concern for others.

Lacking resources to support such programs, many U.S. schools have implemented *zero tolerance policies,* which severely punish all disruptive and threatening behavior, major and minor, usually with suspension or expulsion. Yet often these policies are applied inconsistently: Low-SES minority students are two to three times as likely to be punished, especially for minor misbehaviors (Goode & Goode, 2007; Skiba & Rausch, 2006). No evidence exists that zero tolerance achieves its objective of reducing youth aggression and other forms of misconduct (Stinchcomb, Bazemore, & Riestenberg, 2006). To the contrary, some studies find that by excluding students from school, zero tolerance heightens high school dropout and antisocial behavior.

Comprehensive Approaches According to many researchers, effective treatment for serious, violent juvenile offenders must be multifaceted, encompassing parent training, social understanding, relating to others, and self-control. A program called EQUIP uses positive peer culture—an adult-guided but adolescent-conducted small group approach aimed at creating a prosocial climate. By themselves, peer-culture groups do not reduce antisocial behavior. Rather, they sometimes perpetuate deviant peer influences (Dodge, Dishion, & Lansford, 2006). But in EQUIP, the approach is supplemented with training in social skills, anger management, correction of cognitive distortions, and moral reasoning (DiBiase et al., 2011; Gibbs et al., 2009b). Delinquents who participated in EQUIP displayed improved social skills and conduct during the following year compared with controls receiving no intervention. Also, the more advanced moral reasoning that emerged during group meetings seemed to have a long-term impact on antisocial youths' ability to inhibit lawbreaking behavior (Leeman, Gibbs, & Fuller, 1993).

Yet even multidimensional treatments can fall short if young people remain embedded in hostile home lives, poor-quality schools, antisocial peer groups, and violent neighborhoods. In another program, called *multisystemic therapy,* counselors trained parents in communication, monitoring, and discipline skills; integrated violent youths into positive school, work, and leisure activities; and disengaged them from deviant peers. Compared with individual therapy, random assignment to the intervention led to improved parent–adolescent relationships and school performance and to a dramatic drop in number of arrests that persisted for two decades after treatment and—when participants did commit crimes—to a reduction in their severity (see Figure 12.7). Multisystemic therapy also helped limit family instability in adulthood, as measured by involvement in civil suits over divorce, paternity, or child support (Borduin, 2007; Henggeler et al., 2009; Sawyer & Borduin, 2011). Efforts to create nonaggressive environments—at the family, community, and cultural levels—are needed to help antisocial youths and to foster healthy development of all young people.

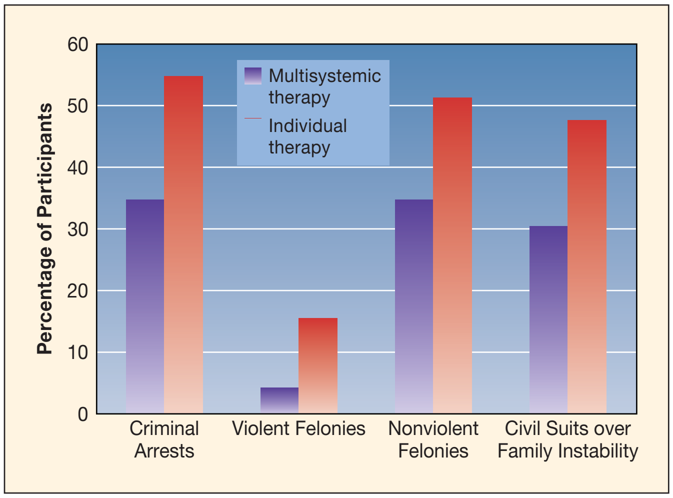


FIGURE 12.7 **Impact of multisystemic therapy on arrests and family-related civil suits 22 years after treatment.** A follow-up of violent youths two decades after treatment revealed that compared with participants who had been randomly assigned to individual therapy, those assigned to multisystemic therapy had fewer criminal arrests overall and—when they did commit crimes—were far less likely to perpetrate violent offenses. In addition multisystemic therapy recipients displayed reduced family instability, as measured by civil suits over divorce, paternity, or child support—evidence of more favorable adult adjustment. (Adapted from Sawyer & Borduin, 2011.)

Review ■ Cite factors that contribute to an improved ability to delay gratification from early to middle childhood.

Connect ■ Reread the section on adolescent parenthood in Chapter 5 (pages 217–219) and the section on adolescent suicide in Chapter 11 (pages 472–473). What factors do these problems have in common with chronic antisocial behavior?

Apply ■ Zeke had been well behaved in elementary school, but around age 13 he started spending time with the "wrong crowd." At 16, he was arrested for property damage. Is Zeke likely to become a long-term offender? Why or why not?

Reflect ■ Describe a recent instance in which your cool processing system dominated your hot-system reactivity, enabling you to resist temptation. What did your cool processing system do to gain control?

SUMMARY

Morality as Rooted in Human Nature (p. 486)

Describe and evaluate the biological perspective on morality.

- Morality is grounded in our genetic heritage, perhaps through prewired emotional reactions. We share many morally relevant behaviors with other species, and areas within the prefrontal cortex are vital for emotional responsiveness to others' suffering. However, mature expression of moral emotions requires strong caregiving supports and cognitive attainments.

Morality as the Adoption of Societal Norms (p. 488)

Describe and evaluate the psychoanalytic perspective on moral development.

- Both psychoanalytic and social learning theories regard moral development as a process of **internalization** of societal standards. According to Freud, morality emerges between ages 3 and 6, when the Oedipus and Electra conflicts are resolved with formation of the superego. The child adopts the moral standards of the same-sex parent and redirects hostile impulses toward the self in the form of guilt.
- Although guilt is an important motivator of moral action, contrary to Freud's view, discipline promoting fear of punishment and loss of parental love does not foster conscience development. **Induction** is far more effective and also fosters a strong **moral identity.**
- Contrary to Freud's belief, moral development is not complete by the end of early childhood. Rather, it proceeds gradually, extending into adulthood.

Describe and evaluate the social learning perspective on moral development.

- Social learning theory focuses on how moral behavior is learned through reinforcement and modeling. Effective models are warm, responsive, competent, powerful, and consistent in words and deeds. By middle childhood, children have internalized prosocial rules.
- Frequent harsh punishment results in weak moral internalization and wide-ranging adjustment problems, models aggressive behavior, and can spiral into serious abuse. Alternatives such as **time out** and withdrawal of privileges can help parents avoid these undesirable effects, as long as parents apply the techniques consistently, maintain a warm relationship with the child, and offer explanations for punishment.
- The most effective discipline relies on positive parenting, which encourages good conduct by building a mutually respectful bond with the child.

Cite central features of the cognitive-developmental approach to moral development.

- The cognitive-developmental approach assumes that individuals, rather than internalizing existing rules and expectations, develop morally through **construction**—actively thinking about situations in which social conflicts arise and attaining new moral understandings.

Morality as Social Understanding (p. 496)

Describe and evaluate Piaget's theory of moral development.

- Piaget, whose work inspired the cognitive-developmental perspective on morality, identified two stages: **heteronomous morality,** in which children view moral rules in terms of **realism,** and the **morality of cooperation,** in which children regard rules as flexible, socially agreed-on principles and base fairness on **ideal reciprocity.**
- Piaget's theory accurately describes the general direction of moral development but underestimates young children's moral capacities. Preschool and early school-age children consider intentions when making moral judgments, although they interpret intentions rigidly. They also have differentiated notions about the legitimacy of authority figures. For nonmoral concerns, they base authority on knowledge, not social position.

Describe Kohlberg's theory of moral development, and discuss research on his stages.

- Kohlberg viewed moral development as a gradual process extending into adolescence and adulthood. Using clinical interviewing, he constructed a sequence of moral reasoning based on responses to hypothetical dilemmas.
- Kohlberg concluded that moral reasoning gradually advances through three levels, each containing two stages: At the **preconventional level,** morality is viewed as externally controlled and actions are judged by their consequences; at the **conventional level,** conformity to laws and rules is regarded as necessary for societal order; and at the **postconventional level,** morality is defined by abstract, universal principles and values.

- While most individuals move through Kohlberg's first four stages in the predicted order, his hypothetical moral dilemmas do not address the whole range of strategies people use to resolve real-life moral problems. Because situational factors affect moral reasoning, Kohlberg's stages are best viewed as loosely organized and overlapping.

© BOB DAEMMRICH/PHOTOEDIT

- Kohlberg argued that cognitive and perspective-taking attainments, though vital for moral advances, are not sufficient to ensure them. At present, the domain in which the cognitive prerequisites for mature moral reasoning first emerges—cognitive, social, or moral—remains unclear.
- Contrary to Gilligan's claim, Kohlberg's theory does not underestimate the moral maturity of females but instead taps both justice and caring moralities.

Describe influences on moral reasoning and its relationship to moral behavior.

- Factors contributing to moral maturity include a flexible, open-minded personality; warm, rational parenting; education level, and peer discussions of moral issues.
- In village societies, where moral cooperation is based on direct relations between people, moral reasoning rarely moves beyond Kohlberg's Stage 3. In collectivist cultures, moral dilemma responses are more other-directed than in Western societies.
- Maturity of moral reasoning is only modestly related to moral behavior. Moral action is also influenced by the individual's emotions, temperament, history of morally relevant experiences and intuitions, and moral identity.
- Despite declines in formal religious involvement in adolescence, most religiously affiliated teenagers are advantaged in moral values and behavior.

Discuss challenges to Kohlberg's theory.

- In a revised conception of moral development, moral maturity is achieved at Kohlberg's Stages 3 and 4, when young people grasp ideal reciprocity—attainments that require profound moral constructions. Some critics favor a pragmatic approach in which moral judgments are viewed as practical tools that people use to achieve their goals.

How do children distinguish moral imperatives from social conventions and matters of personal choice?

- Even preschoolers show a basic grasp of justice, distinguishing **moral imperatives** from **social conventions** and **matters of personal choice.** Through actively making sense of people's everyday social experiences and emotional reactions, young children conclude that moral (but not social conventional) transgressions are wrong in any context.
- School-age children gradually clarify and link moral imperatives and social conventions, taking into account the purpose of the rule; people's intentions, knowledge, and beliefs; and the context of people's behavior. The conviction that certain matters are up to the individual strengthens with age, especially in adolescence. Notions of personal choice foster moral understanding of individual rights.

Development of Morally Relevant Self-Control (p. 514)

Discuss the development of morally relevant self-control, noting implications of individual differences for cognitive and social competencies.

- Self-control emerges in the second year in the form of **compliance.** The capacity for **delay of gratification** increases steadily between ages 1½ and 3 years and is influenced by temperament and quality of caregiving.
- School-age children become better at devising their own strategies for resisting temptation, leading to a flexible capacity for **moral self-regulation.** Individual differences in delay of gratification predict diverse cognitive and social competencies, including effective social problem solving and positive peer relations.

The Other Side of Self-Control: Development of Aggression (p. 516)

Discuss the development of aggression, noting various influences, and describe successful interventions.

- Aggression first appears by the second year. Over early and middle childhood, **proactive aggression** declines, while **reactive aggression** increases. Proactive and reactive aggression come in at least three forms: **physical aggression, verbal aggression,** and **relational aggression.**
- During early childhood, physical aggression decreases, while verbal aggression increases. By age 17 months, boys are more physically aggressive than girls. Teacher-and peer-reported aggression declines in adolescence, but delinquent acts increase, especially for boys.
- Children high in physical or relational aggression tend to remain so over time. Irritable, fearless, impulsive, and overactive children are at risk for aggression, but whether or not they become so depends on child-rearing conditions.
- Children who are products of strife-ridden families and harsh, inconsistent discipline develop social-cognitive deficits and distortions that contribute to long-term maintenance of aggression. Widespread poverty, harsh living conditions, and inadequate schools increase antisocial acts among children and adolescents.
- Training parents in effective child-rearing techniques and teaching children alternative ways of resolving conflict help reduce aggression. Social-cognitive interventions aimed at improving social information processing and perspective taking are also beneficial. The most effective interventions address the multiple factors that sustain antisocial behavior.

Developing Non-Gender-Stereotyped Children

On a typical morning in our university laboratory preschool, 4-year-old Jenny eagerly entered the housekeeping corner and put on a frilly long dress. Karen, setting the table nearby, produced whimpering sound effects for the baby doll in the crib. Jenny lifted the doll, sat down in the rocking chair, and whispered, “You're hungry, aren't you?” A moment later, Jenny announced, “This baby won't eat. I think she's sick. Ask Rachel if she'll be the nurse.” Karen ran to find Rachel, who was coloring at the art table.

Meanwhile, Nathan called to Tommy, “Wanna play traffic?” Both boys dashed energetically toward the cars and trucks in the block corner. Soon David joined them. “I'll be policeman first!” announced Nathan, climbing onto a chair. “Green light, go!” shouted the young police officer. With this signal, Tommy and David scurried on all fours around the chair, each pushing a large wooden truck. “Red light!” exclaimed Nathan, and the trucks screeched to a halt.

“My truck beat yours,” Tommy informed David.

“Only 'cause I need gas,” David responded.

“Let's build a runway for the trucks,” suggested Nathan. The three construction engineers began gathering large blocks for the task.

At an early age, children adopt many gender-linked standards of their culture. Jenny, Karen, and Rachel use dresses, dolls, and household props to act out a stereotypically feminine scene of nurturance. In contrast, Nathan, Tommy, and David's play is active, competitive, and masculine in theme. And both boys and girls interact more with agemates of their own sex.

Why are young children's play and social preferences so strongly gender-typed, and how do these attitudes and behaviors change with age? Do societal expectations affect children's views of themselves as masculine or feminine beings, thereby limiting their potential? To what extent do widely held beliefs about the characteristics of males and females reflect reality? Is it true that the average boy is aggressive and competitive, with good spatial and mathematical skills, whereas the average girl is passive and nurturant, with superior verbal skills? How large are differences between the sexes, and in what ways do heredity and environment contribute to them? These are the central questions asked by researchers studying gender typing. In this chapter, we will answer each of them.

Perhaps more than any other area of child development, the study of gender typing has responded to societal change. Until the early 1970s, psychologists regarded the adoption of gender-typed beliefs and behaviors as essential for healthy adjustment. Since then, this view has changed, largely because of progress in women's rights. Today, many people recognize that some gender-typed characteristics, such as extreme aggressiveness and competitiveness on the part of males and passivity and conformity on the part of females, are serious threats to mental health.

Consistent with this realization, the study of gender typing has undergone theoretical revision. Major current approaches are social learning theory, with its emphasis on modeling and reinforcement, and cognitive-developmental theory, with its focus on children as active thinkers about their social world. But neither is sufficient by itself. An information-processing view, *gender schema theory,* combines elements of both theories to explain how children acquire gender-typed knowledge.

- Explain how the study of gender typing has responded to societal change.

Central to our discussion is a set of special terms. Two involve the public face of gender in society. **Gender stereotypes** are widely held beliefs about characteristics deemed appropriate for males and females. **Gender roles** are the reflection of these stereotypes in everyday behavior. A third, **gender identity,** is the private face of gender—perception of the self as relatively masculine or feminine in characteristics. Finally, **gender typing** refers broadly to any association of objects, activities, roles, or traits with biological sex in ways that conform to cultural stereotypes of gender and, therefore, encompasses all the gender-linked responses just mentioned (Liben & Bigler, 2002). As we explore each facet of gender typing in children and adolescents, you will see that biological, cognitive, and social factors are involved.

- Describe the development of gender stereotyping from early childhood into adolescence.
- Cite individual and group differences in gender stereotyping, and discuss the relationship between gender stereotyping and gender-role adoption.

Gender Stereotypes and Gender Roles

Gender stereotypes have appeared in religious, philosophical, and literary works for centuries. Consider the following excerpts, from ancient times to the present:

- "Woman is more compassionate than man and has a greater propensity to tears. . . . But the male . . . is more disposed to give assistance in danger, and is more courageous than the female." (Aristotle, cited in Miles, 1935)
- "A man will say what he knows, a woman says what will please." (Jean-Jacques Rousseau, *Emile,* 1762/1955)
- "Man with the head and woman with the heart; Man to command and woman to obey; All else confusion." (Alfred, Lord Tennyson, *Home They Brought Her Warrior,* 1842)
- "Love is a mood—no more—to a man, And love to a woman is life or death." (Ella Wheeler Wilcox, *Blind,* 1882)
- "Men do not confront a relationship problem unless absolutely necessary because the risk is that they'll make things much worse. . . . Women seek out even small problems to prevent them from becoming more serious." (Lewis, *Why Don't You Understand? A Gender Relationship Dictionary,* 2009)

Although the past four decades have brought a new level of awareness about the wide range of roles possible for each gender, strong beliefs about sex differences remain. In the 1960s, researchers began asking people what personality characteristics they consider typical of men and women. Widespread agreement emerged in many studies. As Table 13.1 illustrates, **instrumental traits,** reflecting competence, rationality, and assertiveness, were regarded as masculine; **expressive traits,** emphasizing warmth, caring, and sensitivity, were viewed as feminine. Despite intense political activism promoting gender equality in the 1970s and 1980s, these stereotypes remain essentially unchanged (Lueptow, Garovich, & Lueptow, 2001; Ruble, Martin, & Berenbaum, 2006; Vonk & Ashmore, 2003). Furthermore, cross-cultural research conducted in 30 nations reveals that the instrumental–expressive dichotomy is a widely held stereotype around the world (Williams & Best, 1990).

Besides personality traits, other gender stereotypes exist. These include physical characteristics (tall, strong, and sturdy for men; soft, dainty, and graceful for women), occupations (truck driver, insurance agent, and chemist for men; elementary school teacher, secretary, and nurse for women), and activities or behaviors (good

TABLE 13.1 **Personality Traits Regarded as Stereotypically Masculine or Feminine**

MASCULINE TRAITS	FEMININE TRAITS
Active	Aware of others' feelings
Acts as a leader	Considerate
Adventurous	Cries easily
Aggressive	Devotes self to others
Ambitious	Emotional
Competitive	Excitable in a major crisis
Doesn't give up easily	Feelings hurt easily
Dominant	Gentle
Feels superior	Home-oriented
Holds up well under pressure	Kind
Independent	Likes children
Makes decisions easily	Neat
Not easily influenced	Needs approval
Outspoken	Passive
Rough	Tactful
Self-confident	Understanding of others
Takes a stand	Warm in relations with others

at fixing things and at leading groups for men; good at child care and decorating the home for women) (Biernat, 1991; Powlishta et al., 2001).

The variety of attributes consistently identified as masculine or feminine, their broad acceptance, and their stability over time suggest that gender stereotypes are deeply ingrained patterns of thinking. What's more, they cast men in a generally positive light and women in a generally negative light. The traits, activities, and roles associated with the male gender are more numerous, diverse, and desirable than those associated with the female gender. For example, in Western cultures, stereotypically masculine occupations are far more numerous than feminine occupations (Liben & Bigler, 2002). And only a few masculine attributes, such as "aggressive" and "criminal," are negative; the overwhelming majority are advantageous and high-status. Feminine attributes, in contrast, are mostly unfavorable and low-status.

Adults apply gender stereotypes to children with a special intensity. In a study in which 20- to 40-year-olds were shown photos of children and adults and asked to rate each on "masculine," "feminine," and "neutral" personality traits, adults differentiated boys from girls more sharply than they did men from women (see Figure 13.1) (Powlishta, 2000). Given that many adults view children through a gender-biased lens, perhaps it is not surprising that by the second year, children have begun to absorb these messages.

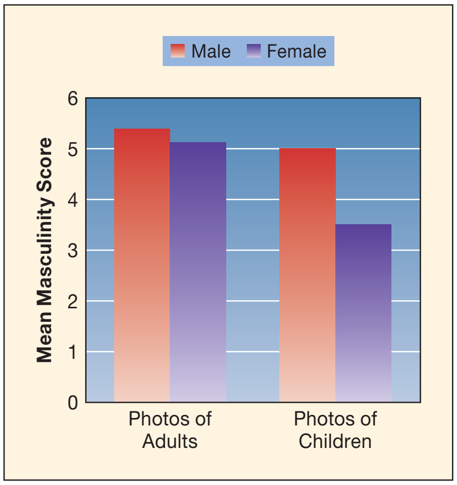

FIGURE 13.1 Adults' ratings of photos of adults and children on "masculine" personality traits. Adults perceived little difference in the adult photos but a sharp difference in the child photos, rating boys as far more "masculine" in personality traits than girls. Ratings for "feminine" personality traits were similar: Adults reported far greater difference between boys and girls than between men and women. (Adapted from Powlishta, 2000.)

Gender Stereotyping in Early Childhood

Recall from Chapter 11 that between 18 months and 3 years, children label their own and others' sex, using such words as *boy* and *girl* and *lady* and *man*. As children sort out what these categories mean in terms of activities and behaviors, gender stereotypes appear and expand rapidly. Before age 2, children have begun to acquire subtle associations with gender that most of us hold—men as rough and sharp, women as soft and round. In one study, 18-month-olds linked such items as fir trees and hammers with males, although they had not yet learned comparable feminine associations (Eichstedt et al., 2002). Preschoolers associate toys, articles of clothing, tools, household items, games, occupations, colors (pink and blue), and behaviors (relational and physical aggression) with one sex or the other (Banse et al., 2010; Giles & Heyman, 2005; Poulin-Dubois et al., 2002). They have even acquired gender-stereotyped metaphors—"bears are for boys"; "butterflies are for girls" (Leinbach, Hort, & Fagot, 1997).

During early childhood, gender-stereotyped beliefs strengthen—so much so that many children apply them as blanket rules rather than flexible guidelines. When children were asked whether gender stereotypes could be violated, half or more of 3- and 4-year-olds answered "no" to clothing, hairstyle, and play with certain toys (Barbie dolls and G.I. Joes) (Blakemore, 2003). Furthermore, most 3- to 6-year-olds are firm about not wanting to be friends with a child who violates a gender stereotype (a boy who wears nail polish, a girl who plays with trucks) or to attend a school where such violations are allowed (Ruble et al., 2007).

Striking evidence that young children view their world in strongly gender-stereotyped terms also comes from studies in which researchers labeled a target child as a boy or a girl and then provided either gender-typical or gender-atypical information about the target's characteristics. Then they asked children to rate the target on additional gender-stereotypic attributes. Preschoolers usually relied only on the gender label in making judgments, ignoring the specific information (Biernat, 1991; Martin, 1989). For example, when told "Tommy is a boy. Tommy's best friend is a girl, and Tommy likes to play house," children under age 6 nevertheless said that Tommy would much rather play with cars and train engines than with sewing machines and dolls.

The rigidity of preschoolers' gender stereotypes helps us understand some commonly observed everyday behaviors. Shown a picture of a Scottish bagpiper wearing a kilt, 4-year-olds are likely to insist, "Men don't wear skirts!" During free play, they exclaim that girls can't

© LAURA DWIGHT PHOTOGRAPHY

Gender-stereotyped beliefs strengthen during early childhood. These preschoolers would probably say "no" to the suggestion that a boy be allowed to join their tea party.

be police officers and boys can't take care of babies. These one-sided judgments are a joint product of gender stereotyping in the environment and young children's cognitive limitations—in particular, their difficulty coordinating conflicting sources of information. Most preschoolers do not yet realize that characteristics *associated with* being male or female—activities, toys, occupations, hairstyle, and clothing—do not *determine* a person's sex. They have trouble understanding that males and females can be different in terms of their bodies but similar in many other ways.

Gender Stereotyping in Middle Childhood and Adolescence

By age 5, gender stereotyping of activities and occupations is well-established. During middle childhood and adolescence, knowledge of stereotypes increases in the less obvious areas of personality traits and achievement (Serbin, Powlishta, & Gulko, 1993; Signorella, Bigler, & Liben, 1993). At the same time, because older children realize that gender-stereotypic attributes are associated—but not defining—features of gender, their beliefs about possible male and female characteristics and capacities become more flexible (Banse et al., 2010; Martin, Ruble, & Szkrybalo, 2002).

Personality Traits

To assess stereotyping of personality traits, researchers ask children to assign "masculine" adjectives ("tough," "rational," "cruel") and "feminine" adjectives ("gentle," "affectionate," "dependent") to either a male or a female stimulus figure. Recall from Chapter 11 that not until middle childhood are children good at sizing up people's dispositions. This same finding carries over to awareness of gender stereotypes.

Research in many countries reveals that stereotyping of personality traits increases steadily in middle childhood, becoming adultlike around age 11 (Best, 2001; Heyman & Legare, 2004). A large Canadian study examined the pattern of children's trait learning and found that the stereotypes acquired first reflected *in-group favoritism.* Kindergartners through second graders had greatest knowledge of trait stereotypes that portrayed their own gender in a positive light (Serbin, Powlishta, & Gulko, 1993). Once trait stereotyping is well under way, children characterize the in-group and the out-group as having both positive and negative qualities. Though both boys and girls view each gender as having more positive than negative traits, this effect is stronger for the in-group—evidence that in-group favoritism persists. And girls express greater in-group favoritism and out-group negativity than boys (Powlishta et al., 1994; Susskind & Hodges, 2009). Perhaps girls more readily pick up the widely held general impression of girls as "sugar and spice and everything nice" and of boys as "snakes and snails and puppy dog tails."

Achievement Areas

Shortly after entering elementary school, children figure out which academic subjects and skill areas are "masculine" and which are "feminine." They often regard reading, spelling, art, and music as more for girls and mathematics, athletics, and mechanical skills as more for boys (Cvencek, Meltzoff, & Greenwald, 2011; Eccles, Jacobs, & Harold, 1990; Jacobs & Weisz, 1994). These stereotypes influence children's preferences for and sense of competence at certain subjects. For example, in both Asian and Western nations, boys tend to feel more competent than girls at math, science, and athletics, whereas girls feel more competent than boys at language arts—even when children of equal skill level are compared (Bhanot & Jovanovic, 2005; Hong, Veach, & Lawrenz, 2003; Kurtz-Costes et al., 2008).

An encouraging sign is that some gender-stereotyped beliefs about achievement may be changing. In several recent investigations carried out in Canada, France, and the United

States, a majority of elementary and secondary school students disagreed with the idea that math is a "masculine" subject (Martinot & Désert, 2007; Plante, Théoret, & Favreau, 2009; Rowley et al., 2007). And when Canadian students were given the option of rating math as a "feminine" subject (not offered in previous studies), an impressive number—though more girls than boys—expressed the view that it is predominantly feminine. The overwhelming majority of these young people, however, continued to view language arts traditionally—as largely "feminine." And they still perceived girls to do better in language arts than in math.

Toward Greater Flexibility Although school-age children are knowledgeable about a wide variety of gender stereotypes, they also develop a more open-minded view of what males and females *can do,* a trend that continues into adolescence.

In studying gender stereotyping, researchers usually ask children whether or not both genders can display a personality trait or activity—a response that measures **gender-stereotype flexibility,** or overlap in the characteristics of males and females. In a German study that followed children from ages 5 to 10, regardless of the degree of early gender-stereotype rigidity, flexibility increased dramatically from age 7 on (see Figure 13.2) (Trautner et al., 2005). As they develop the capacity to integrate conflicting social cues, children realize that a person's sex is not a certain predictor of his or her personality traits, activities, and behavior. Similarly, by the end of the school years, most children no longer view gender-typed behavior (especially that of girls) as inborn and fixed. Rather, they see it as socially influenced—affected by home rearing environments (Taylor, 1996; Taylor, Rhodes, & Gelman, 2009).

But acknowledging that boys and girls *can* cross gender lines does not mean that children always *approve* of doing so. In one longitudinal study, between ages 7 and 13, children of both genders became more open-minded about girls being offered the same opportunities as boys. This change, however, was less pronounced for boys (Crouter et al., 2007). Moreover, school-age children seem well aware of the power of such male in-group favoritism to limit girls' access to high-status opportunities. When 5- to 10-year-olds were asked why only men had been elected to the U.S. presidency, their most frequent explanation was that men would not vote for a woman candidate (Bigler et al., 2008).

Furthermore, many school-age children take a harsh view of certain violations, such as boys playing with dolls and wearing girls' clothing and girls acting noisily or roughly. They are especially intolerant when boys engage in these "cross-gender" acts, which children regard as nearly as bad as moral transgressions (Blakemore, 2003; Levy, Taylor, & Gelman, 1995). When asked for open-ended descriptions of boys and girls, children most often mention girls' physical appearance ("is pretty," "wears dresses") and boys' activities and personality traits ("likes trucks," "is rough") (Miller et al., 2009). The salience of these stereotypes helps explain why, when children of the other sex display the behaviors just mentioned, they are likely to experience severe peer disapproval.

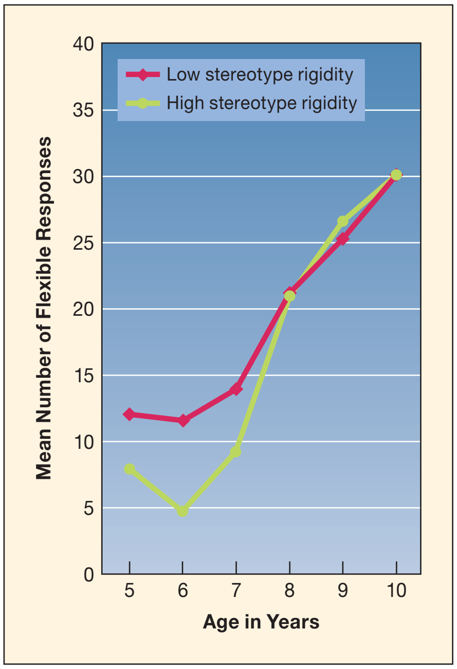

FIGURE 13.2 Changes in gender-stereotype flexibility between ages 5 and 10. In a longitudinal study, German schoolchildren responded annually to a questionnaire assessing the flexibility of their gender-stereotyped beliefs (whether they thought both genders could display a personality trait or activity). Children differing in degree of gender-stereotype rigidity at age 5 eventually became equally flexible. Findings support the powerful role of cognitive changes in inducing flexibility, since early individual differences in rigidity were not sustained. (From H. M. Trautner et al., 2005, "Rigidity and Flexibility of Gender Stereotypes in Childhood: Developmental or Differential?," *Infant and Child Development, 14,* p. 371. Copyright © 2005 John Wiley & Sons Limited. Reprinted with permission.)

Individual and Group Differences in Gender Stereotyping

By middle childhood, almost all children have acquired extensive knowledge of gender stereotypes. But they vary widely in the makeup of their understanding. The various components of gender stereotyping—activities, behaviors, occupations, and personality traits—do not correlate highly: A child may be highly knowledgeable in one area without being knowledgeable in the others (Serbin, Powlishta, & Gulko, 1993). This suggests that gender typing is like "an intricate puzzle that the child pieces together in a rather idiosyncratic way" (Hort, Leinbach, & Fagot, 1991, p. 196). To build a coherent notion of gender, children must assemble many elements. The precise pattern in which they acquire the pieces, the rate at which they do so, and the flexibility of their beliefs vary greatly from child to child.

Group differences in gender stereotyping also exist. The strongest of these is sex-related: Boys tend to hold more gender-stereotyped views than girls throughout childhood and adolescence (Steele, 2003; Turner, Gervai, & Hinde, 1993). But as we have seen, stereotyping of math as masculine seems to have declined, even among boys. And in one study, adolescents of both sexes, responding to vignettes about hypothetical high-achieving peers, expressed greater liking for the high-achieving girls (Quatman, Sokolik, & Smith, 2000). A heartening possibility is that boys are beginning to view gender roles as encompassing more varied possibilities.

© LAURA DWIGHT PHOTOGRAPHY

Even children who are well-versed in gender-related expectations are not necessarily highly gender-typed in their everyday activities. This boy appears to view playing with dolls as appropriate for boys as well as girls.

The limited evidence available on ethnic minorities suggests that African-American children hold less stereotyped views of activities and achievement areas than do Caucasian-American children (Bardwell, Cochran, & Walker, 1986; Rowley et al., 2007). Perhaps this is partly a response to the less traditional gender roles seen in African-American families—for example, more employed mothers and mother-headed households (U.S. Census Bureau, 2011b). In adolescence and adulthood, higher-SES individuals tend to hold more flexible gender-stereotyped views than their lower-SES counterparts (Lackey, 1989; Serbin, Powlishta, & Gulko, 1993). Years of schooling and a wider array of life options may contribute to this difference.

Gender Stereotyping and Gender-Role Adoption

Does gender-stereotyped thinking influence children's gender-role adoption, thereby restricting their experiences and potential? The evidence is mixed. Gender-typed preferences and behaviors increase sharply over the preschool years—the same period in which children rapidly acquire stereotypes. And boys—the more stereotyped of the two sexes—show greater conformity to their gender role (Bussey & Bandura, 1992; Ruble, Martin, & Berenbaum, 2006).

But these parallel patterns do not tell us whether gender stereotyping shapes children's behavior. In some cases, a reverse direction of influence may operate because certain gender-role preferences are acquired long before children know much about stereotypes. For example, by the middle of the second year, boys and girls favor different toys. When researchers showed 18-month-olds paired photos of vehicles and dolls, boys looked longer than girls at the vehicles, whereas girls looked longer than boys at the dolls (see Figure 13.3) (Serbin et al., 2001).

Furthermore, children who are well-versed in gender-related expectations are sometimes highly gender-typed, and sometimes not, in their everyday activities (Downs & Langlois, 1988; Serbin, Powlishta, & Gulko, 1993; Weinraub et al., 1984). Why might this be so? First, we have seen that children master the components of gender-stereotyped knowledge in diverse ways, each of which may have different implications for their behavior. Second, by middle childhood, virtually all children know a great deal about gender stereotypes—knowledge so universal that it cannot predict variations in their behavior.

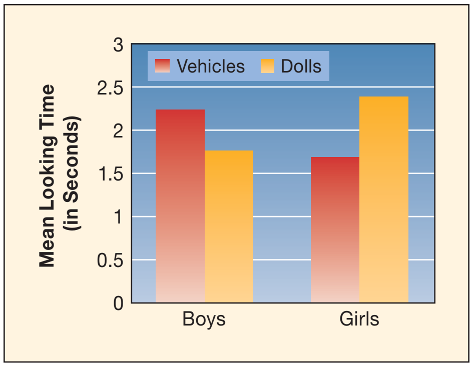

FIGURE 13.3 Eighteen-month-old girls' and boys' looking times at vehicles and dolls. Already, gender-role preferences are evident: Boys looked longer at the vehicles, whereas girls looked longer at the dolls. (Adapted from Serbin et al., 2001.)

Rather than stereotype knowledge, stereotype flexibility is a good predictor of children's gender-role adoption in middle childhood. Children who believe that many stereotyped characteristics are appropriate for both sexes (for example, that it is OK for girls to play with trucks) are more likely to cross gender lines in choosing activities, playmates, and occupational roles (Liben, Bigler, & Krogh, 2002; Serbin, Powlishta, & Gulko, 1993; Signorella, Bigler, & Liben, 1993). This suggests that gender stereotypes affect behavior only when children incorporate those beliefs into their gender identities—self-perceptions of what they can and should do at play, in school, and as future participants in society. Now let's turn to various influences that promote children's gender-typed beliefs and behaviors.

ASK YOURSELF

Review ■ Explain how young children's cognitive limitations combine with the social environment to contribute to rigid gender stereotyping in early childhood.

Review ■ What factors allow for flexibility in gender stereotyping in middle childhood and adolescence? How is gender-stereotype flexibility related to gender-typed preferences and behavior?

Connect ■ Describe parallels between the development of gender and ethnic attitudes (see Chapter 11, pages 477–478).

Apply ■ After 9-year-old Dennis enrolled in an after-school cooking class, his friends Tom and Bill began teaing him relentlessly. Cite evidence that explains this negative reaction to Dennis's "cross-gender" behavior.

Influences on Gender Stereotyping and Gender-Role Adoption

- Discuss biological influences on gender stereotyping and gender-role adoption.
- Discuss environmental influences on gender stereotyping and gender-role adoption.

According to social learning theorists, gender-stereotyped knowledge and behaviors are transmitted to children through direct teaching. As we will see shortly, much research is consistent with this view. Others argue, however, that biological makeup leads each sex to be uniquely suited to particular roles and that most societies do little more than encourage gender differences that are genetically based. Is there evidence to support this idea?

Biological Influences

Although practically no contemporary theorist would argue that "biology is destiny," serious questions about biological influences on gender typing remain. According to an evolutionary perspective, the adult life of our male ancestors was largely oriented toward competing for mates, that of our female ancestors toward rearing children. Therefore, males became genetically primed for dominance and females for intimacy, responsiveness, and cooperativeness. These sex differences in behavior exist in 97 percent of mammalian species, including chimpanzees, our closest evolutionary relative (de Waal, 1993, 2001). Evolutionary theorists claim that family and cultural forces can influence the intensity of biologically based sex differences, leading some individuals to be more gender-typed than others. But experience cannot eradicate aspects of gender typing that served adaptive functions in human history (Geary, 1999; Maccoby, 2002).

Two sources of evidence have been used to support the role of biology: (1) cross-cultural similarities in gender stereotypes and gender-role adoption and (2) the influence of hormones on gender-role behavior. Let's examine each in turn.

How Much Cross-Cultural Similarity Exists in Gender Typing?

Earlier in this chapter, we noted that the instrumental–expressive dichotomy is reflected in the gender stereotyping of many national groups. Although this finding fits with the idea that social influences simply build on genetic differences between the sexes, we must be cautious in drawing this conclusion.

A close look at cross-cultural findings reveals that most societies promote instrumental traits in males and expressive traits in females, although great diversity exists in the magnitude of this difference (Konner, 2010; Munroe & Romney, 2006; Whiting & Edwards, 1988b). For example, in Nyansongo, a small agricultural settlement in Kenya, mothers work four to five hours a day in the gardens, while older siblings care for young children, tend the cooking fire, and wash dishes. Because these duties are assigned to children of both sexes, girls do not have total responsibility for "feminine" tasks and have more time to interact with agemates. Their greater freedom and independence lead them to score higher than girls of

In the wake of devastating floods, a Bangladeshi girl breaks bricks with her mother. Although most societies promote instrumental traits in males and expressive traits in females, current conditions may alter the extent of this difference.

CULTURAL INFLUENCES

Sweden's Commitment to Gender Equality

Among all nations in the world, Sweden is unique in the value it places on gender equality. More than a century ago, Sweden's ruling political party adopted equality as a central goal. One social class was not to exploit another, nor one gender another. In the 1960s, Sweden's expanding economy attracted women into the labor force in large numbers, raising the question of who would help sustain family life. Calling on the principle of equality, the Swedish people responded: fathers, just like mothers (Plantin, Mansson, & Kearney, 2003).

The Swedish "equal roles family model" maintains that husband and wife should have the same opportunity to pursue a career and should be equally responsible for housework and child care. To support this goal, Swedish fathers have had the right to paid parental employment leave longer than fathers in any other nation—since 1974. Today, in addition to two weeks of postbirth leave, Swedish fathers and mothers may share a total of 16 months of full leave at 80 percent of prior income, which can be taken any time before the child reaches 8 years of age (Swedish Social Insurance Agency, 2011a). In addition, Sweden made child-care centers available, so toddlers and preschoolers could be cared for outside the home. Otherwise, a class of less privileged women might be exploited for caregiving and domestic work—an outcome that would contradict the principle of equality.

According to several indicators, Sweden's family model is very successful. Child-care centers are numerous, of high quality, and heavily subsidized by the government. Over 80 percent of mothers of infants and preschoolers are employed, and although Swedish fathers do not yet share housework and child care equally with mothers, they are more involved than fathers in the United States and other Western European nations (Dribe & Stanfors, 2009). Today, 90 percent of Swedish fathers take at least some parental employment leave—more than in any other nation in the world. And more than half make work adjustments—reducing work hours, turning down promotions, and refusing overtime—so they can spend additional time with children (Haas, 2003; Haas, Chronholm, & Hwang, 2006). Furthermore, Sweden has instituted "daddy-months," allocating two of the 16 months leave to fathers, which if not used are lost—a reform aimed at encouraging fathers to take more responsibility for child rearing. Consequently, over the past decade, fathers' leave use nearly doubled, from 12 to 23 percent of total leave time available (Swedish Social Insurance Agency, 2011b).

Has Sweden's progressive family policy affected the gender beliefs and behaviors of its population? A study of Swedish and American adolescents found that valuing of the "masculine" over the "feminine" role was less pronounced in Sweden than in the United States. Swedish young people regarded each gender as a blend of instrumental and expressive traits, and they more often viewed gender roles as a matter of learned tasks and domains of expertise than as inborn traits or rights and duties (Intons-Peterson, 1988). Similarly, large nationally representative surveys in Western European countries reveal that Swedish adults hold more favorable attitudes toward maternal employment. For example, more Swedish than British and Norwegian respondents agreed that "a working mother could establish just as warm and secure a relationship with her children as a mother who does not work" (Knudsen & Waerness, 2003).

Traditional gender typing has not been eradicated in Sweden. But great progress has been made as a result of steadfastly pursuing a program of gender equality.

© MIKAEL UTTERSTRÖM/ALAMY

In Sweden, which highly values gender equality, fathers are more involved in child care than in other Western nations. Parents share 16 months of paid leave, with two "daddy-months" specifically allotted to fathers.

other tribal and village cultures in dominance, assertiveness, and playful roughhousing. In contrast, boys' caregiving responsibilities mean that they often display help-giving and emotional support (Whiting & Edwards, 1988a). Among industrialized nations, Sweden is widely recognized as a society in which traditional gender-linked beliefs and behaviors are considerably reduced (see the Cultural Influences box above).

These examples indicate that experience can profoundly influence gender typing. Nevertheless, reversals of traditional gender roles are rare. Because cross-cultural findings are inconclusive, scientists have turned to a more direct test of the importance of biology: the impact of sex hormones on gender typing.

Sex Hormones and Gender Typing In Chapters 3 and 5, we discussed how genetic makeup, mediated by hormones, regulates sexual development and body growth. Sex hormones also affect brain development and neural activity in many animal species, and they do so in humans as well (Hines & Green, 1991). Are hormones, which so pervasively affect body structures, also important in gender-role adoption?

Play Styles and Preference for Same-Sex Peers. Experiments with animals reveal that prenatally administered androgens (male sex hormones) increase active play in both male and female mammals. Androgens also promote male-typical sexual behavior and aggression and suppress maternal caregiving in a wide variety of species (Lephart et al., 2001; Sato et al., 2004).

Eleanor Maccoby (1998) argues that at least some of these hormonal effects extend to humans. Recall from the introduction to this chapter that as early as the preschool years, children seek out playmates of their own sex—a preference observed in many mammalian species and cultures (Beatty, 1992; Munroe & Romney, 2006). At age 4, children spend three times as much time with same-sex as with other-sex playmates. By age 6, this ratio has climbed to 11 to 1 (Martin & Fabes, 2001). Throughout the school years, children continue to show a strong preference for same-sex peers.

Why is gender segregation so widespread and persistent? According to Maccoby, early on, hormones affect play styles, leading to rough, noisy movements among boys and to calm, gentle actions among girls. Then, as children interact with peers, they choose partners whose interests and behaviors are compatible with their own. By age 2, girls appear overwhelmed by boys' rambunctious behavior and retreat from it (Benenson, Apostoleris, & Parnass, 1997). Nonhuman primates react similarly (Beatty, 1992). When a male juvenile initiates rough, physical play, male peers join in, whereas females withdraw.

During the preschool years, girls increasingly seek out other girls and like to play in pairs because of a common preference for quieter activities involving cooperative roles. Boys come to prefer larger-group play with other boys, who share a desire to run, climb, play-fight, compete, and build up and knock down (Fabes, Martin, & Hanish, 2003). Social pressures for "gender-appropriate" play and cognitive factors—in particular, gender stereotyping, the tendency to evaluate members of one's own sex more positively, and expectations of negative reactions from others for play with other-sex children—also contribute to gender segregation (Ruble, Martin, & Berenbaum, 2006).

Nevertheless, sex hormones are involved. In one study, prenatal levels of the androgen hormone testosterone (measured in amniotic fluid samples collected during amniocentesis) positively predicted "masculine"-style play in both boys and girls when they were followed up during middle childhood (Auyeung et al., 2009). Studies of exceptional sexual development are consistent with these findings.

***Exceptional Sexual Development**.* *Congenital adrenal hyperplasia (CAH)* is a disorder in which a genetic defect causes the adrenal system to produce unusually high levels of androgens from the prenatal period onward. Although the physical development of boys remains unaffected, girls with CAH are usually born with masculinized external genitals. Most undergo surgical correction in infancy, followed by continuous drug therapy to overcome the hormone imbalance.

Interview and observational studies support the conclusion that prenatal androgen exposure influences certain aspects of "masculine" gender-role behavior. Compared with

Sex hormones are believed to influence preschoolers' tendency to choose same-sex partners who share their play style—cooperative play in pairs among girls, noisy roughhousing in groups among boys. But social pressures also promote gender segregation.

other girls, girls with CAH tend to be higher in activity level; to like cars, trucks, and blocks better than dolls; to prefer boys as playmates; and to be more interested in "masculine" careers, such as truck driver, soldier, or pilot (Beltz, Swanson, & Berenbaum, 2011; Cohen-Bendahan, van de Beek, & Berenbaum, 2005; Pasterski et al., 2011). The greater CAH girls' exposure to prenatal androgens, the more "masculine" their play and career interests (Hall et al., 2004; Servin et al., 2003). Furthermore, although girls with CAH receive more parental encouragement to play with girls' toys than do their unaffected sisters, they nevertheless prefer boys' toys—whether playing alone or in the presence of their mother or father (Pasterski et al., 2005).

Fewer studies are available on genetic males with abnormally low early androgen exposure. In *androgen insensitivity syndrome,* the testes produce normal levels of androgens, but androgen receptors in body cells are partially or completely impaired. In other conditions, androgen production by the testes is reduced. Depending on the extent of impairment, physical outcomes range from predominantly male to typically female urogenital tract and external genitals. In one study of such children, degree of reduction in prenatal androgen exposure predicted feminine gender-typed behavior, including toy choices, play behaviors, and preference for girl playmates (Jürgensen et al., 2007). Nevertheless, all children with complete androgen insensitivity syndrome were reared as girls. And children with partial androgen effects reared as girls displayed more feminine behavior than those reared as boys—findings suggesting a role for child rearing.

Other research on individuals reared from infancy as members of the other sex because they had ambiguous genitals indicates that most accepted their assigned sexual identity, though a substantial minority of CAH girls with masculinized genitals expressed considerable discomfort with being reared female (Slijper et al., 1998). Investigators attributed this outcome to both biological and social factors, including hormonal influences on the brain and parents' struggles over sex assignment, which in some cases resulted in negative attitudes toward their daughters. (Some parents, because of their baby's masculinized genitals, had initially assigned the male sex but, after determination of genetic sex, reassigned the infant to the female sex.).

Taken together, research indicates that sex hormones influence gender typing, with the most consistent findings involving activity level and associated preferences for "gender-appropriate" play, toys, and careers. But as we will see next, we must be careful not to minimize the role of experience.

Environmental Influences

In a study following almost 14,000 British children from ages 2½ to 8, gender-typed behavior was remarkably stable: The most gender-typed young preschoolers developed into the most gender-typed school-age children (Golombok et al., 2008). Although prenatal hormone exposure may predispose certain children to be more gender-typed, a wealth of evidence reveals that environmental forces provide powerful support for gender-role adoption. Adults view boys and girls differently and treat them differently. In addition, children's social contexts—home, school, and community—offer many opportunities to observe males and females behaving in gender-stereotyped ways. And beginning in early childhood, peers vigorously promote gender typing.

Perceptions and Expectations of Adults

When adults are asked to observe neutrally dressed infants who are labeled as either boy or girl, they "see" qualities that fit with the baby's artificially assigned sex. In research of this kind, adults tend to rate infants' physical features and (to a lesser extent) their personality traits in a gender-stereotyped fashion (Stern & Karraker, 1989; Vogel et al., 1991). Boys, for example, are viewed as firmer, larger, better coordinated, and hardier; girls as softer, finer featured, more delicate, and less alert.

During childhood and adolescence, parents continue to hold different perceptions and expectations of their sons and daughters. They want their preschoolers to play with "gender-appropriate" toys and, with respect to child-rearing values, describe achievement, competition, and control of emotion as important for sons and warmth, "ladylike" behavior, and closely supervised activities as important for daughters (Brody, 1999; Turner & Gervai, 1995). Furthermore, when asked about attitudes toward "cross-gender" behavior, parents of preschoolers responded more negatively to the idea of boys than of girls crossing gender lines (Sandnabba & Ahlberg, 1999).

Treatment by Parents Do adults actually treat children in accord with stereotypical beliefs? A combined analysis of many studies reported that on the whole, differences in the way parents socialize boys and girls are small (Lytton & Romney, 1991). This does not mean that parental treatment is unimportant. It simply indicates that if we generalize across age periods, contexts, and behaviors, we find only a few clear trends. When the evidence is examined closely, however, consistent effects emerge. Younger children receive more direct training in gender roles than older children—a finding that is not surprising, given that gender typing occurs especially rapidly during early childhood (Golombok et al., 2008). And wide variation from study to study suggests that some parents practice differential treatment far more intensely than others.

© MICHAEL NEWMAN/PHOTOEDIT

As his clothing, bedroom décor, and toys attest, this toddler's parents have already begun to promote gender-typed preferences and behaviors.

Infancy and Early Childhood. In infancy and early childhood, parents encourage a diverse array of gender-specific play activities and behaviors. As early as the first few months—before children can express their own preferences—parents create different environments for boys and girls. Bedrooms are decorated with distinct colors and themes. Parents give sons toys that stress action and competition (guns, cars, tools, and footballs) and daughters toys that emphasize nurturance, cooperation, and physical attractiveness (dolls, tea sets, jump ropes, and jewelry) (Leaper, 1994; Leaper & Friedman, 2007).

Parents also actively reinforce independence in boys and closeness and dependency in girls. For example, parents react more positively when a son plays with cars and trucks, demands attention, runs and climbs, or tries to take toys from others. When interacting with daughters, they more often direct play activities, provide help, encourage participation in household tasks, engage in conversation, make supportive statements (approval, praise, and agreement), and refer to emotions (Clearfield & Nelson, 2006; Fagot & Hagan, 1991; Kuebli, Butler, & Fivush, 1995). Gender-typed play contexts amplify these communication differences. For example, when playing housekeeping, mothers engage in high rates of supportive emotional talk with girls (Leaper, 2000).

As these findings suggest, language is a powerful *indirect* means for teaching children about gender stereotypes and gender roles. Earlier in this chapter, we saw that most young children hold rigid beliefs about gender. Although their strict views are due in part to cognitive limitations, they also draw on relevant social experiences to construct these views. Like ethnic biases discussed in Chapter 11 (see page 476), young children's gender biases often bear little resemblance to those of their parents (Tenenbaum & Leaper, 2002). But even parents who believe strongly in gender equality unconsciously use language that highlights gender distinctions and informs children about traditional gender roles (see the Social Issues: Education box on pages 540–541).

Early in development, then, parents provide many experiences—through play materials and social interaction—that promote assertiveness, exploration, engagement with the physical world, and emotional restraint in boys and imitation, reliance on others, and emotional sensitivity in girls. These experiences, in turn, give young children a rich array of cues for constructing a view of the world that emphasizes stereotypical gender distinctions.

Middle Childhood and Adolescence. As children's skills expand during the school years, issues of achievement become more salient to parents. Observations of mothers and fathers interacting with their youngsters in teaching situations reveal that parents continue to demand greater independence from boys. When a child requests help, parents are more likely to ignore or refuse to respond to a son but to help a daughter right away. In helping a

SOCIAL ISSUES: EDUCATION

Children Learn About Gender Through Mother–Child Conversations

In an investigation of the power of language to shape children's beliefs and expectations about gender, mothers were asked to converse with their 2- to 6-year-olds about picture books containing images of male and female children and adults engaged in various activities, half consistent and half inconsistent with gender stereotypes. Each picture was accompanied by the question, "Who can X?" where X was the activity on the page.

One mother, who believed in gender equality, turned to a picture of a boy driving a boat and asked, "Who's driving the boat?"

Her 4-year-old son replied, "A sail-man."

The mother affirmed, "A sail-man. Yup, a sailor." Then she asked, "Who can be a sailor? Boys and girls?"

"Boys," the child replied.

"Boys . . . OK," the mother again affirmed.

The child stated more decisively, "Only boys."

Again the mother agreed, "Only boys," and turned the page (Gelman, Taylor, & Nguyen, 2004, p. 104).

A detailed analysis of picture-book conversations revealed that mothers' directly expressed attitudes about gender stereotypes were neutral, largely because, like this mother, they typically posed questions to their children. But by age 4, children often voiced stereotypes, and—nearly one-third of the time—mothers affirmed them! Some mothers either moved on with the conversation or repeated the question, as in the conversation above, but rarely—just 2 percent of the time—did they explicitly counter a child's stereotype, and usually only when the book itself included stereotype-inconsistent pictures.

Although the researchers did not ask mothers to discuss gender, the mothers called attention to it even when they did not need to do so. In the English language, many nouns referring to people convey age-related information *(kid, baby, 2-year-old, preschooler, teenager, grownup, senior),* whereas only a few encode gender *(male, female, sister, brother, aunt, uncle).* Yet when using a noun to refer to a person, mothers explicitly called attention to gender more than half the time, even though the people shown in the books varied as much in age (children versus adults) as in gender. Mothers labeled gender, either with nouns or with pronouns (which in English always refer to gender), especially often when conversing with 2-year-olds: "Is that a he or a she?" "That's a boy." "There's a girl." Such statements encourage toddlers to sort their social world into gender categories, even when the statements themselves do not explicitly convey stereotypes.

Furthermore, both mothers and children frequently expressed *generic utterances*—ones

© ELLEN B. SENISI PHOTOGRAPHY

While reading, this mother may unconsciously teach her child to see the world in gender-linked terms—by referring to gender unnecessarily or by making generic gender statements ("Most girls prefer X"; "Boys usually don't like X").

child with a task, parents behave in a more mastery-oriented fashion with sons, pointing out important features of tasks and setting higher standards—particularly during gender-typed pursuits, such as science activities (Crowley et al., 2001; Tenenbaum & Leaper, 2003). For example, when asked to play with magnets with their 5- and 9-year-olds, mothers engaged in more talk about scientific concepts and principles and more often suggested how to use the magnets imaginatively (for construction and in make-believe play) with sons than with daughters (see Figure 13.4) (Tenenbaum et al., 2005). Mothers' scientific talk at age 9 predicted children's science reading comprehension two years later, in sixth grade.

Consistent with their interaction patterns, parents hold gender-differentiated perceptions of and expectations for children's

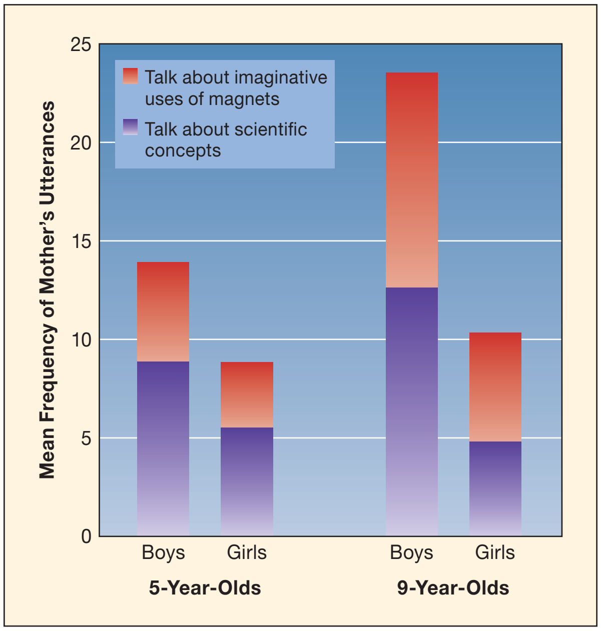

FIGURE 13.4 Mothers' science-related talk while playing with magnets with their 5- and 9-year-old children. Mothers and children were given a powerful magnet and some small metal and plastic objects and asked to play with them. At both ages, mothers engaged in more talk about scientific concepts and imaginative uses of magnets with boys than with girls—a difference especially large at age 9. (Adapted from Tenenbaum et al., 2005.)

that were broad in scope, referring to many, or nearly all, males and females: "Boys can be sailors." "Most girls don't like trucks." Even generics that were gender-neutral ("Lots of girls in this book") or denied a stereotype ("Boys can be ballet dancers, too.") prompted children to view individuals of the same gender as alike and to ignore exceptions. As we will see later in this chapter, generics promote gender-role conformity: Statements such as "This toy is for girls" induce children to prefer the toy labeled for their own sex and to avoid the toy labeled for the other sex.

Mothers' and children's use of generics increased sharply between ages 2 and 6, a period in which gender stereotyping and gender-role conformity rise dramatically (see Figure 13.5). Initially, mothers led the way in generic talk; at age 2, they introduced these category-wide generalizations nearly three times as often as children. By age 6, however, children were producing generics more often than mothers. In addition, mother–child pairs produced more generics about males than about females, and generics were especially common in speech to and from boys, who are the more gender typed of the two sexes.

Even though these mothers overwhelmingly believed in gender equality, they did little to instill those ideas in their children. To the contrary, their most common response to children's stereotypical comments was to affirm them!

In this way, even without directly teaching stereotypes, parents—through language—provide a wealth of implicit cues that enable children to readily construct them.

Adults can combat stereotypical thinking in children through concerted efforts to avoid gendered language. Here are some suggestions:

- Refrain from labeling gender when it is unnecessary, substituting *child, friend, adult,* or *person* for *boy, girl, man,* or *woman.*
- Substitute references to individuals ("That person wants to be a firefighter") for generic expressions, or use qualifiers ("Some boys and some girls want to be firefighters").
- Monitor your own inclination to affirm children's stereotypical claims, countering these as often as possible.
- Discuss gender biases in language with children, pointing out how words can shape inappropriate beliefs and expectations and asking children to avoid using gender labels and generics.

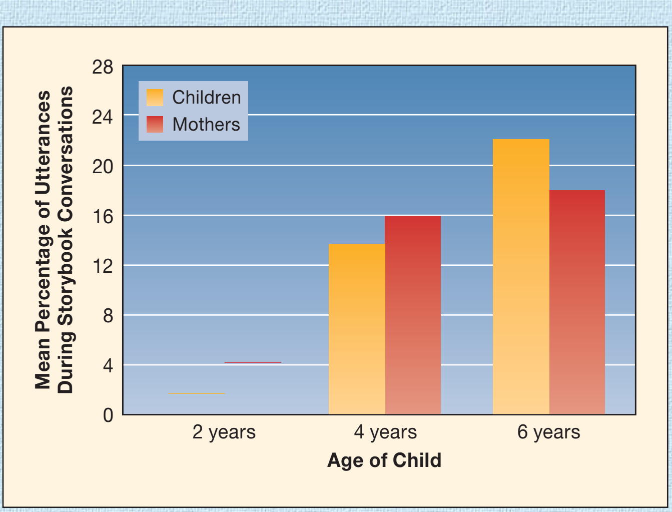

FIGURE 13.5 **Mothers' and children's use of generic references to gender during storybook conversations.** Mothers' and children's use of generics increased dramatically between ages 2 and 6. At age 2, mothers produced more generics than children. By age 6, children produced more generics than mothers. (From S. A. Gelman, M. G. Taylor, & S. P. Nguyen, "Mother–Child Conversations About Gender," *Monographs of the Society for Research in Child Development, 69* [1, Serial No. 275], p. 46. Copyright © 2004, John Wiley and Sons. Reprinted by permission of John Wiley and Sons.)

competencies in various school subjects. Mothers rate girls as better at English than boys who earn similar English grades (Frome & Eccles, 1998). And in longitudinal research, mothers rated first-grade sons as more competent than daughters at math, regardless of their child's actual performance. Maternal gender-typed judgments, in turn, influenced children's self-perceptions of math ability, the effort they devoted to math, and later math achievement, with lasting consequences (Eccles et al., 2000; Jacobs & Eccles, 1992). When the participants were followed up two years after high school graduation and again at age 24 to 25, mothers' early perceptions no longer predicted sons' outcomes. But they continued to predict daughters' self-perceptions and also their career choices. Young women whose mothers had regarded them as highly capable at math were far more likely to choose a physical science career (Bleeker & Jacobs, 2004). Yet mothers rarely made such optimistic judgments about girls.

In related research, investigators had 10- and 13-year-olds and their mothers and fathers choose courses for the children to take when they reached secondary school. Afterward, the children and parents discussed their decisions. Parents selected more language arts courses for daughters and more science courses for sons—trends also evident in children's choices. Especially striking were parents' gender-biased comments during the discussions, with daughters receiving twice as many discouraging remarks as sons across all types of courses—language arts, math, and science ("math is really hard," "that's not where your skills lie") (Tenenbaum, 2009).

LOOK and LISTEN

Watch several parents conversing with their preschoolers about picture books. How many times did the parent make generic statements about gender? How about the child? Did the parent accept or correct the child's generic utterances?

Parents' differential treatment extends to the freedom granted children in their everyday lives. Parents tend to use more directive speech (imperatives and specific suggestions) with girls than with boys (Leaper, Anderson, & Sanders, 1998). And when insisting that children meet their daily responsibilities, mothers of sons more often pair control with autonomy granting. Whereas they usually ask boys to make decisions ("When do you think would be a good time for you to do your music practice?"), parents tend to decide for girls ("Do your practicing right after dinner") (Pomerantz & Ruble, 1998b). Although school-age children interpret parental control without autonomy granting as well-intentioned guidance, they also say it makes them feel incompetent (Pomerantz & Ruble, 1998a).

Other signs of boys' greater freedom are evident in parental willingness to let them range farther from home without supervision and in assignment of chores. In many cultures, girls are given tasks such as food preparation, cleaning, and baby-sitting that keep them close to home, whereas boys are given responsibilities that take them into the surrounding world, such as yard work and errands (Whiting & Edwards, 1988a). As noted earlier, when cultural circumstances require children to perform "cross-gender" chores (as in Nyansongo), the range of behaviors practiced expands.

Do these findings suggest that children in Western cultures be assigned more "cross-gender" tasks? The consequences of doing so are not straightforward. When fathers hold stereotypical views yet their sons engage in "feminine" housework, boys experience strain in the father–child relationship, feel stressed by their responsibilities, and judge themselves as less competent (McHale et al., 1990). In contrast, a match between parental values and nontraditional child-rearing practices leads to a reduction in children's gender stereotyping and gender-role behavior and to an increase in girls' nontraditional career aspirations (Tenenbaum & Leaper, 2002; Turner & Gervai, 1995; Weisner & Wilson-Mitchell, 1990). Furthermore, in homes where fathers devote as much or more time to child care as mothers, children tend to be less gender-typed in emotional expression—sons more emotionally sensitive, daughters more self-confident (Brody, 1997).

Mothers versus Fathers. In most aspects of differential treatment of boys and girls, fathers discriminate the most. For example, in Chapter 10 we saw that fathers tend to engage in more physically stimulating play with their infant sons than daughters, whereas mothers tend to play more quietly with babies of both sexes. In childhood, fathers more than mothers encourage "gender-appropriate" behavior, and they place more pressure to achieve on sons than on daughters (Gervai, Turner, & Hinde, 1995; Wood, Desmarais, & Gugula, 2002).

Parents also seem especially committed to ensuring the gender typing of children of their own sex. While mothers go on shopping trips and bake cookies with their daughters, fathers play catch, help coach Saturday morning soccer games, and take their sons fishing. In addition to spending more time with children of their own sex, parents are more vigilant about monitoring the activities of same-sex children while the children are away from home (Leaper, 2002; Tucker, McHale, & Crouter, 2003). This pattern of greater involvement with same-sex children is another aspect of gender-role training that tends to be more pronounced for fathers (Parke, 1996).

By encouraging girls into adult-structured activities, preschool teachers provide them with extra practice in "feminine" gender-role behaviors—compliance, help-seeking, and patient waiting.

Treatment by Teachers

In some ways, preschool and elementary school teachers reinforce children of both sexes for "feminine" rather than "masculine" behavior. In classrooms, men and women teachers alike usually value obedience and discourage assertiveness (Fagot, 1985a). This "feminine bias" is believed to promote discomfort for boys in school, but it may be as harmful—or even more so—for girls, who willingly conform, with possible long-term negative consequences for their sense of independence and self-esteem.

Teachers also act in ways that maintain and even extend gender roles taught at home. Like parents, preschool teachers give girls more encouragement to participate in adult-structured activities. Girls frequently cluster around the teacher following directions, whereas boys are attracted to play areas where adults are minimally involved (Campbell, Shirley, & Candy, 2004; Powlishta, Serbin, & Moller, 1993). As a result, boys and girls practice different social behaviors. Compliance and bids for help occur more often in adult-structured contexts; assertiveness, leadership, and creative use of materials in unstructured pursuits.

In addition, teachers often emphasize gender distinctions, as when they say, "Will the girls line up on one side and the boys on the other?" or "Boys, I wish you'd quiet down like the girls!"—labeling that promotes gender stereotyping, in-group favoritism, and out-group prejudice in children (Bigler, 1995). At the same time, teachers interrupt girls more than boys during conversation, thereby promoting boys' social dominance and girls' passivity. By age 4, children respond in kind: Boys interrupt their female teachers more than girls do (Hendrick & Stange, 1991).

As early as kindergarten, teachers give more overall attention (both positive and negative) to boys than to girls—a difference evident in diverse countries, including China, England, and the United States. They tend to praise boys more for their academic knowledge, perhaps as a means of motivating them because boys' grades are lower than girls'. And although teachers discourage unruliness in all children, they do so more frequently and forcefully with boys (Chen & Rao, 2011; Davies, 2008; Swinson & Harrop, 2009). When girls misbehave, teachers are more likely to negotiate, coming up with a joint plan to improve their conduct (Erden & Wolfgang, 2004). Teachers' more frequent use of disapproval and controlling discipline with boys seems to result from an expectation that boys will misbehave more often than girls—a belief based partly on boys' actual behavior and partly on gender stereotypes.

The opportunity to assist a female veterinarian prompts this adolescent to picture herself doing similar work, rather than viewing veterinary medicine traditionally, as a male occupation.

Observational Learning

In addition to direct pressures from adults, numerous gender-typed models are available in children's environments. Despite societal changes, children continue to encounter many people in their schools and communities who conform to traditional gender roles—women as elementary school teachers, nurses, and librarians; men as school principals, computer experts, and airline pilots. In one study, researchers presented school-age children, adolescents, and college students with visual and verbal descriptions of novel occupations, in which they varied the sex of the worker and the personal value the job fulfills (money, power, altruism, time for family). At all ages, participants expressed greater interest in occupations held by workers of their own sex than identical jobs held by workers of the other sex—results confirming that merely observing sex differences in occupations affects interest in those fields (Weisgram, Bigler, & Liben, 2010). In addition, males of all ages were especially attracted to jobs depicted as highly paid, females to jobs high in altruism—values that likely contribute to the gender sorting typically seen in the workforce.

Media portrayals are also gender typed. As we will see in Chapter 15, gender roles in television programs have changed little in recent years. And gender stereotypes are especially prevalent in cartoons, music television (MTV), TV commercials, and video games (Calvert et al., 2003; Dietz, 1998; Kahlenberg & Hein, 2010). In addition, despite an increase in gender-equitable storybooks and textbooks, many children read older books in which males are main characters, take center stage in exciting plot activities, and display assertiveness and creativity, while females are submissive, dependent, and passive (Tepper & Cassidy, 1999; Turner-Bowker, 1996). And in a study of award-winning picture books for young children, fathers were represented only half as often as mothers and, when they were included, rarely expressed affection or participated in caregiving but, instead, seemed disengaged from the parenting role (Anderson & Hamilton, 2005).

When children are exposed to nonstereotyped models, they are less traditional in their beliefs and behaviors. Children who often see their parents cross traditional gender lines—mothers who are employed or who do "masculine" household tasks (repairing appliances, washing the car), fathers who do "feminine" household tasks (ironing, cooking, child care)—less often endorse gender stereotypes (Turner & Gervai, 1995; Updegraff, McHale, & Crouter,

LOOK and LISTEN

Keep a list of instances of gender typing that you notice for an entire day—in peoples' jobs, gender-role behaviors, media portrayals, and other. How prevalent are gender-typed models in your environment?

1996). Girls with career-oriented mothers show special benefits. They are more likely to engage in typically masculine activities (such as physically active play), have higher educational aspirations, and hold nontraditional career goals (Hoffman, 2000).

Furthermore, among children of divorced parents, boys in father-absent homes and girls in mother-absent homes are less gender-typed, perhaps because they have fewer opportunities to observe traditional gender roles than in a two-parent household (Brenes, Eisenberg, & Helmstadter, 1985; Williams, Radin, & Allegro, 1992). And compared with agemates in two-parent families, children from single-parent homes are more likely to have at least one other-sex friend (Kovacs, Parker, & Hoffman, 1996).

Peers Because most children associate almost exclusively with peers of their own sex, the peer context is an especially potent source of gender-role learning. In a study in which researchers followed preschoolers and kindergartners over the school year, children who spent more time playing with same-sex partners in the fall showed greater gains in gender typing—in terms of toy choices, activity level, aggression, and extent of play near adults—in the spring (Martin & Fabes, 2001).

© CINDY CHARLES/PHOTOEDIT

These boys positively reinforce one another's gender-typed play. Preschoolers, especially boys, tend to be intolerant of peers who play with "cross-gender" toys, criticizing and pressuring them to change their behavior.

Gender-Role Learning in Gender-Segregated Peer Groups. By age 3, same-sex peers positively reinforce one another for gender-typed play by praising, imitating, or joining in. In contrast, when children engage in "cross-gender" activities—for example, when boys play with dolls or girls with cars and trucks—peers criticize, pressure them to change their behavior, and in extreme cases harass and physically attack them. Boys are especially intolerant of "cross-gender" play in other boys (Fagot, 1984; Langlois & Downs, 1980; Thorne, 1993). A boy who frequently crosses gender lines is likely to be ostracized by other boys, even when he does engage in "masculine" activities!

Children also develop different styles of social influence in gender-segregated peer groups. To get their way in large-group play, boys often rely on commands, threats, and physical force. Girls' preference for playing in pairs leads to greater concern with a partner's needs, evident in girls' use of polite requests, persuasion, and acceptance. Girls soon find that these gentle tactics succeed with other girls but not with boys, who ignore their courteous overtures (Leaper, 1994; Leaper, Tenenbaum, & Shaffer, 1999). Boys' unresponsiveness gives girls another reason to stop interacting with them.

Over time, children come to believe in the "correctness" of gender-segregated play, which further strengthens gender segregation and stereotyped activities. In one study, 3- to 6-year-olds believed that peers would be more likely to approve of their behavior if they played with same-sex agemates—a conviction that predicted children's association with same-sex peers (Martin et al., 1999). As boys and girls separate, in-group favoritism becomes another factor that sustains the separate social worlds of boys and girls, resulting in "two distinct subcultures" of shared knowledge, beliefs, interests, and behaviors (Maccoby, 2002; Ruble, Martin, & Berenbaum, 2006).

Some educators believe that forming mixed-sex activity groups in classroom and recreational settings is a vital means of reducing gender stereotyping and broadening developmental possibilities for both sexes. To be successful, however, interventions may have to modify the styles of social influence typically learned in same-sex peer relations. Otherwise, boys are likely to dominate and girls to react passively, thereby strengthening traditional gender roles and the stereotypes each sex holds of the other.

In addition, modifying children's direct pressures on peers to conform to traditional gender roles is vital. To explore one successful intervention, in which children themselves learn to challenge peers' sexist remarks, turn to the Social Issues: Education box on the following page.

LOOK and LISTEN

While observing 3- to 5-year-olds during a free-play period in a preschool or child-care program, note the extent of gender segregation and gender-typed play. Did styles of social influence differ in boys' and girls' gender-segregated groups? Jot down examples.

SOCIAL ISSUES: EDUCATION

Teaching Children to Challenge Peers' Sexist Remarks

Rose approached Tony and Aaron, who were swinging on a tire in the schoolyard, and asked, "Can I get on, too?"

"No! This is a boys' game," Tony responded.

Jerry, who overheard Tony's refusal, called out, "Hey, Tony! You can't say that girls can't play!"

Peers, as we have seen, play a prominent role in encouraging children to adopt traditional gender-role attitudes and behavior. Hence, challenges like Jerry's are extremely rare in children's interactions with agemates. Can children be taught to confront peers' sexist remarks, which endorse biological sex as a legitimate basis for limiting individual roles and behaviors? If so, the impact could be powerful. Because children's sexist statements often occur out of adults' earshot, gender stereotyping within the peer group is difficult for adults to modify. Inducing peers to confront such remarks might be far more effective in getting children to be more accepting of peers who cross gender lines.

© LAURA DWIGHT PHOTOGRAPHY

Children who are explicitly taught to confront peers' sexist remarks are more likely than others to counter those remarks, creating a climate of respect for boys and girls as individuals.

In an elementary school with an explicit curricular goal of creating a gender-equitable climate where all children—both gender-typical and gender-atypical—feel respected and included, kindergarten through third-grade classes were randomly assigned to one of two interventions aimed at reducing peers' gender-typed remarks (Lamb et al., 2009):

- *Active intervention.* On the basis of evidence that children learn more when they practice new skills and receive feedback on their performance, this condition involved active rehearsal. Children were explicitly taught six rhyming retorts (one per day, in 20-minute sessions) to peers' sexist remarks—for example, for exclusion: "You can't say that boys [girls] can't play!"; for gender-role biases: "Not true, gender doesn't limit you!" After mastering each retort, the children formed small groups in which they practiced the response in short skits they created. This enabled them to apply the retort in familiar situations and also exposed them to peer models doing the same.
- *Narrative intervention.* Children in this condition heard the same six retorts to sexist remarks, embedded in six age-appropriate stories (one per day). However, no opportunity for active rehearsal was offered. Rather, children drew a picture of their favorite part of the story, after which they listened to an additional story depicting a bullying situation and participated in a discussion of the importance of addressing (not ignoring) bullying behaviors.

Compared to children in the narrative intervention, those in the active intervention showed dramatic gains in willingness to challenge peers' sexist remarks in hypothetical scenarios (see Figure 13.6). To see whether this outcome extended to real life, researchers arranged to have participants confronted with a peer's sexist remark in the school hallway. Teachers asked each child to carry an "other-gender" item (such as a purse for boys, a tool belt for girls) to the school office. On the way, a same-sex classmate with acting ability stopped the child and made a sexist comment. Again, active-intervention children more often countered these remarks—an impressive outcome, given that children almost never engage in real-world challenges to gender-typed peer pressure.

At a six-month follow-up, a majority of children in both interventions responded to hypothetical scenarios with retorts to one or more peer sexist remarks. Perhaps active-intervention children, who were willing to confront sexist statements in everyday life, served as effective models for their narrative-intervention classmates, teaching them to challenge peer sexist comments. For girls, long-term active-intervention effects extended beyond behavior to attitudes: They gained in gender-stereotype flexibility.

In sum, a short-term active intervention is successful at getting children to counter peers' sexist statements. The spread of these retorts to other classmates suggests that active training in combating sexism can contribute to a school climate that respects and protects individual differences in children's gender typing.

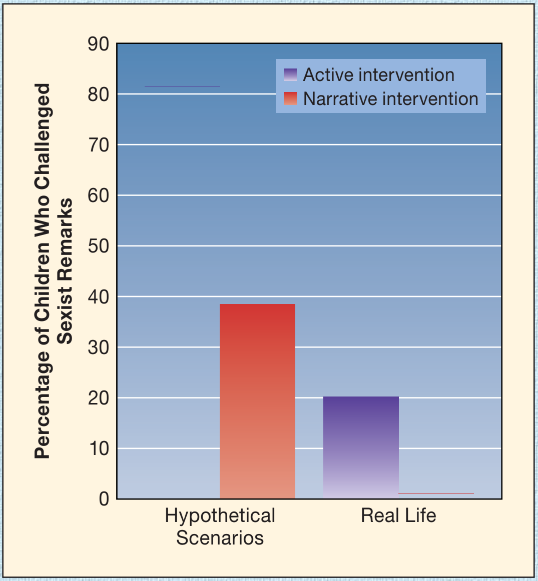

FIGURE 13.6 Challenges to peers' sexist remarks by active-intervention and narrative-intervention children. Prior to intervention, only a handful of children in both conditions challenged peers' sexist remarks. Following intervention, the majority in the active-intervention group responded with one or more challenges in hypothetical scenarios. Real-life challenges, though infrequent, also occurred far more often among active-intervention children. (Adapted from Lamb et al., 2009.)

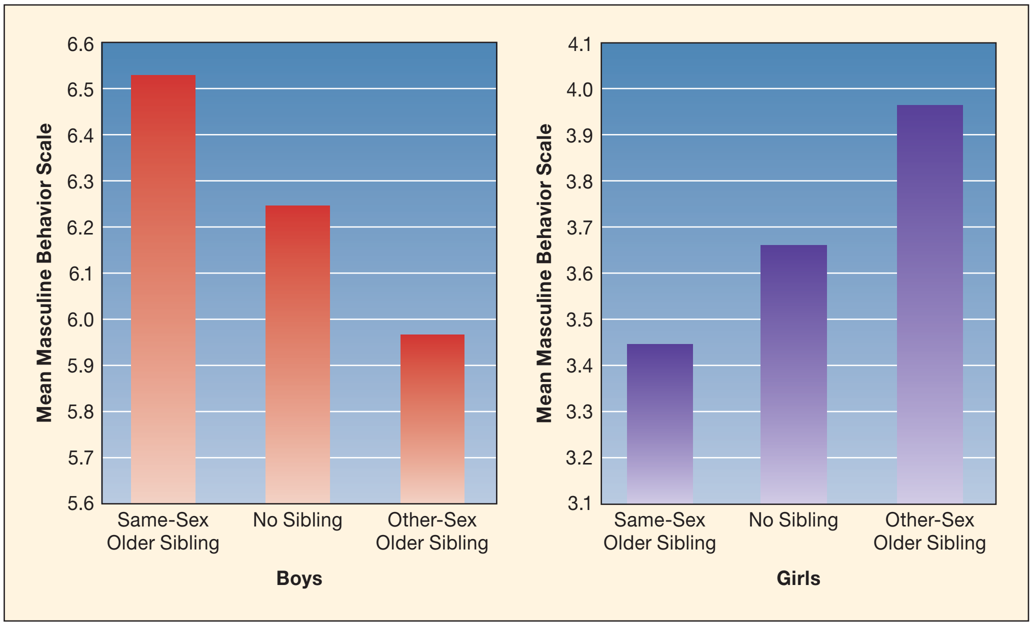
Cultural Variations. Although gender segregation is pervasive, cultures and subcultures differ in the extent of gender-typed communication within those groups. African-American and Hispanic-American lower-SES girls, for example, are generally more assertive and independent in their interactions with one another and with boys than are Caucasian-American girls (Goodwin, 1998). A comparison of Chinese and U.S. preschoolers' play revealed similar differences. Chinese 5-year-old girls used more direct commands, complaints, and critical statements when interacting with both same- and other-sex peers than their American counterparts. And Chinese boys frequently combined commands with warning, appeasing, and justifying statements, which reduced expressions of dominance in boys' playgroups: "Better not open that. You'll spill it." "I'll do it. I'm here to help you!" (Kyratzis & Guo, 2001).

In collectivist societies where group cohesion is highly valued, children may not feel a need to work as hard at maintaining same-sex peer relations through traditional interaction patterns. In addition to reducing children's ethnic prejudices (see Chapter 11), ethnically integrated classrooms might reduce gender-typed peer communication as the cross-gender influence attempts of some children rub off on others.

Siblings Growing up with siblings of the same or the other sex also affects gender typing. But sibling effects are more complex than peer influences because they depend on birth order and family size (McHale, Crouter, & Whiteman, 2003). Whereas younger siblings have little impact on older siblings' gender typing, older siblings serve as powerful models for younger siblings. In a British study, more than 5,000 mothers provided information on play and other behaviors of their 3-year-olds, each of whom had either one older sibling or no siblings. As Figure 13.7 shows, children with same-sex siblings were more gender-typed than children with no siblings, who in turn were more gender-typed than children with other-sex older siblings (Rust et al., 2000). During the school years, older siblings' influence expands, affecting younger siblings' sex-stereotyped attitudes, personality traits, and leisure pursuits (McHale et al., 2001).

Curiously, however, other research contradicts these findings, indicating that children with same-sex siblings are less stereotyped in their interests and personality traits than those from mixed-sex families (Grotevant, 1978; Tauber, 1979). How can we explain these conflicting results? Recall from Chapter 10 that siblings often strive to be different from one another. This effect is strongest when children are of the same sex and come from large

FIGURE 13.7 **"Masculine" behavior scores for preschool boys and girls with same-sex older siblings, other-sex older siblings, and no siblings.** In this British study, 3-year-olds with same-sex older siblings were more gender-typed than children with no siblings, who were more gender-typed than children with other-sex older siblings. Notice how boys with the lowest masculine behavior scores have older sisters, whereas girls with the highest masculine behavior scores have older brothers. (Adapted from Rust et al., 2000.)



families, in which they may feel a greater need to stand out. A close look reveals that studies reporting a *modeling and reinforcement effect* (an increase in gender typing among same-sex siblings) focus on children from two-child families. In contrast, those reporting a *differentiation effect* often include children from larger families.

In addition, parents whose children are all of the same sex sometimes relax pressures toward gender typing. For example, mothers were more willing to give their child a gender-atypical toy as a gift when the child had an older, same-sex sibling (Stoneman, Brody, & MacKinnon, 1986). Also, in all-girl and all-boy families, children are more likely to be assigned "cross-gender" chores because no "gender-appropriate" child is available to do the job. Therefore, families with all same-sex siblings may provide some special opportunities to step out of traditional gender roles.

In sum, older siblings are influential models in young children's gender typing. But aspects of the family context, including family size and parental pressures, can alter this modeling effect.

These brothers share a typically "feminine" task. When siblings are the same sex, they are more likely to be assigned "cross-gender" chores.

ASK YOURSELF

Review ■ Summarize parent, peer, and sibling influences on gender-role adoption. Why are sibling influences more complex than parent and peer influences?

Connect ■ Using research in this chapter and in Chapter 11 (see page 467), explain why girls are more susceptible than boys to learned helplessness in achievement situations.

Apply ■ List findings indicating that language and communication—between parents and children, between teachers and children, and between peers—powerfully affect children's gender stereotyping and gender-role behavior. What recommendations would you make to counteract these influences?

Reflect ■ In early and middle childhood, did you play mostly with peers of your own sex? What gender-linked attitudes and behaviors were emphasized in your peer associations? How did you view members of the other sex?

Gender Identity

- Discuss androgyny as well as social learning and cognitive-developmental views of the development of gender identity in early childhood.
- What changes in gender identity occur in middle childhood and adolescence?
- Explain gender schema theory.

Besides biological and environmental influences, another factor eventually affects gender stereotyping and gender-role behavior: *gender identity,* a person's perception of the self as relatively masculine or feminine in characteristics. In middle childhood, as self-concepts emphasize psychological dispositions over concrete behaviors (see Chapter 11), researchers can measure gender identity by asking children to rate themselves on personality traits. A child or adult with a "masculine" identity scores high on traditionally masculine items *(ambitious, competitive, self-sufficient)* and low on traditionally feminine items *(affectionate, cheerful, soft-spoken)*. Someone with a "feminine" identity does the reverse. Although most people view themselves in gender-typed terms, a substantial minority (especially females) have a gender identity called **androgyny,** scoring high on *both* masculine and feminine personality characteristics.

Gender identity is a good predictor of psychological adjustment. "Masculine" and androgynous children and adults have higher self-esteem than "feminine" individuals (Boldizar, 1991; DiDonato & Berenbaum, 2011; Harter, 2006). In line with their flexible self-definitions, androgynous individuals are more adaptable—able to show masculine independence or feminine sensitivity, depending on the situation (Huyck, 1996; Taylor & Hall, 1982).

A close look at these findings, however, reveals that the masculine component of androgyny is largely responsible for the superior psychological health of androgynous women over those with traditional identities. Feminine women seem to have adjustment difficulties because many of their attributes are not valued highly by society (Bronstein, 2006). Nevertheless, the existence of an androgynous identity demonstrates that children can acquire a mixture of positive qualities traditionally associated with each gender—an orientation that may best help them realize their potential. In a future society in which feminine traits are socially rewarded to the same extent as masculine traits, androgyny may very well represent the ideal personality.

Emergence of Gender Identity

How do children develop a gender identity? According to *social learning theory,* behavior comes before self-perceptions. Preschoolers first acquire gender-typed responses through modeling and reinforcement and only later organize these behaviors into gender-linked ideas about themselves. In contrast, *cognitive-developmental theory* maintains that self-perceptions come before behavior. Over the preschool years, children acquire a cognitive appreciation of the permanence of their sex. They develop **gender constancy**—a full understanding of the biologically based permanence of their gender, which combines three understandings: *gender labeling, gender stability,* and *gender consistency.* Then children use this knowledge to guide their behavior. Let's trace the development of gender constancy during the preschool years.

© SALLY AND RICHARD GREENHILL/ALAMY IMAGES

If this 4-year-old saw her doll dressed in boys' clothing, she likely would claim it had become a boy. She has not yet attained gender consistency—the understanding that sex is biologically based and permanent.

Development of Gender Constancy

Lawrence Kohlberg (1966) proposed that before age 6 or 7, children cannot maintain the constancy of their gender, just as they cannot pass Piagetian conservation problems. They attain this understanding only gradually, by moving through the following stages:

1. **Gender labeling.** By the early preschool years, children can label their own sex and that of others correctly. But when asked such questions as "When you [a girl] grow up, could you ever be a daddy?" or "Could you be a boy if you wanted to?" young children freely answer yes (Slaby & Frey, 1975). And when shown a doll whose hairstyle and clothing are transformed before their eyes, children indicate that the doll's sex has changed (Chauhan, Shastri, & Mohite, 2005; Fagot, 1985b).
2. **Gender stability.** Slightly older preschoolers have a partial understanding of the permanence of sex, in that they grasp its stability over time. But even though they know that male and female babies will eventually become boys and girls and men and women, they continue to insist that changing hairstyle, clothing, or "gender-appropriate" activities will also change a person's sex (Fagot, 1985b; Slaby & Frey, 1975).
3. **Gender consistency.** During the late preschool and early school years, children understand that sex is biologically based and remains the same even if a person dresses in "cross-gender" clothes or engages in nontraditional activities (Emmerich, 1981; Ruble et al., 2007).

Many studies confirm that the development of gender constancy follows this sequence. As Kohlberg assumed, mastery of gender constancy is associated with attainment of conservation (De Lisi & Gallagher, 1991). It is also strongly related to the ability to pass verbal appearance–reality tasks (see page 243 in Chapter 6) (Trautner, Gervai, & Nemeth, 2003). Indeed, gender-consistency tasks can be considered a type of appearance–reality problem, in that children must distinguish what a person looks like from who he or she really is.

In many cultures, young children do not have access to basic biological knowledge about gender because they rarely see members of the other sex naked. But giving children information about genital differences does not result in gender constancy. Preschoolers who have such knowledge usually say that changing a doll's clothing or hairstyle will not change their sex, but when asked to justify their response, they do not refer to sex as an innate, unchanging quality of people (Szkrybalo & Ruble, 1999). This suggests that cognitive immaturity, not social experience, is largely responsible for young children's difficulty grasping the permanence of sex.

How Well Does Gender Constancy Predict Gender-Role Adoption? Is cognitive-developmental theory correct that gender constancy is responsible for children's gender-typed behavior? Evidence for this assumption is weak. "Gender-appropriate" behavior appears so early in the preschool years that its initial appearance must result from modeling and reinforcement, as social learning theory suggests.

Although gender constancy does not initiate gender-role conformity, the cognitive changes that lead up to it do seem to facilitate gender typing. Young children who reach the stage of gender labeling early show more rapid development of "gender-appropriate" play preferences and knowledge of gender stereotypes than their late-labeling peers (Fagot, Leinbach, & O'Boyle, 1992; Zosuls et al., 2009). Similarly, understanding of gender stability prompts increased gender stereotyping, preference for same-sex playmates, choice of "gender-appropriate" toys, and identification with one's gender group (Martin & Little, 1990; Ruble et al., 2007). These findings suggest that as soon as children form basic gender categories, they use them to acquire gender-relevant information about their social world and about themselves.

The stage of gender consistency, in contrast, functions differently. Although outcomes are not entirely consistent, the realization that sex does not change despite superficial transformations in clothing or behavior seems to contribute to increasing gender-stereotype flexibility in the early school years (Ruble et al., 2007). But overall, the impact of gender constancy on gender typing is not great. As we will see next, gender-role adoption is more powerfully affected by children's beliefs about how close the connection must be between their own gender and their behavior.

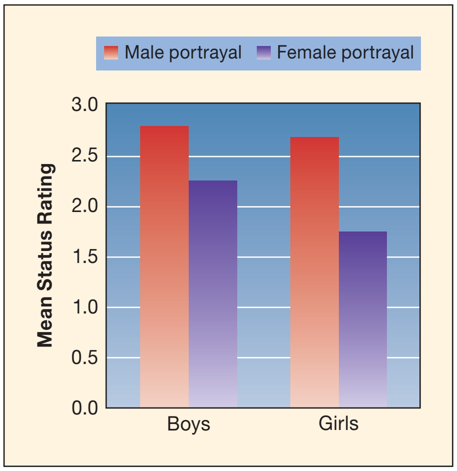
Gender Identity in Middle Childhood

During middle childhood, boys' and girls' gender identities follow different paths. Self-ratings on personality traits reveal that from third to sixth grade, boys strengthen their identification with the "masculine" role, while girls' identification with "feminine" characteristics declines. While still leaning toward the "feminine" side, girls are more androgynous than boys—more likely to describe themselves as having "other-gender" characteristics (Serbin, Powlishta, & Gulko, 1993). This difference is also evident in children's activities. Whereas boys usually stick to "masculine" pursuits, girls experiment with a wider range of options. Besides cooking, sewing, and baby-sitting, they join organized sports teams and work on science projects. And girls are more likely than boys to consider future work roles stereotyped for the other gender, such as firefighter or astronomer (Liben & Bigler, 2002).

These changes are due to a mixture of cognitive and social forces. School-age children of both sexes are aware that society attaches greater prestige to "masculine" characteristics. For example, they rate "masculine" occupations as having higher status than "feminine" occupations. And they more often regard a novel job (such as *clipster,* "a person who tests batteries") as higher in status and as appropriate "for both men and women" when it is portrayed with a male worker than with a female worker (see Figure 13.8 on page 550) (Liben, Bigler, & Krogh, 2001; Weisgram, Bigler, & Liben, 2010). In view of the strong association of males' activities with high status, it is not surprising that girls start to identify with "masculine" traits and are attracted to some typically masculine activities.

As school-age children make social comparisons and characterize themselves in terms of stable dispositions, their gender identity expands to include the following self-evaluations, which greatly affect their adjustment:

FIGURE 13.8 Eleven-year-olds' status ratings of novel jobs portrayed with male and female workers. Although children had no prior knowledge of these jobs and therefore had not previously stereotyped them as "masculine" or "feminine," simply portraying the job with a male worker resulted in higher status ratings. (Adapted from Liben, Bigler, & Krogh, 2001.)



© PETER HVIZDAK/THE IMAGE WORKS

This 9-year-old girl enjoys karate lessons. Whereas school-age boys usually stick to "masculine" pursuits, girls experiment with a wider range of options.

- *Gender typicality*—the degree to which the child feels similar to others of the same gender. Although children need not be highly gender-typed to judge themselves as gender-typical, their psychological well-being depends on feeling, at least to some degree, that they "fit in" with their same-sex peers (Egan & Perry, 2001).
- *Gender contentedness*—the degree to which the child feels comfortable with his or her gender assignment, which also promotes happiness and satisfaction with oneself.
- *Felt pressure to conform to gender roles*—the degree to which the child feels parents and peers disapprove of his or her gender-related traits. Because such pressure reduces the likelihood that children will explore options related to their interests and talents, children who feel strong gender-typed pressure are likely to be distressed and dissatisfied.

In a longitudinal study of third through seventh graders, *gender-typical* and *gender-contented* children gained in self-esteem over the following year. In contrast, children who were *gender-atypical* and *gender-discontented* declined in self-worth. Furthermore, gender-atypical children who reported *intense pressure to conform to gender roles* experienced serious difficulties, in the form of withdrawal, sadness, disappointment, and anxiety (Yunger, Carver, & Perry, 2004).

Clearly, how children feel about themselves in relation to their gender group becomes vitally important in middle childhood, and those who experience rejection because of their gender-atypical traits suffer profoundly. Researchers and therapists are engaged in a heated debate over how best to help children who feel gender-atypical. Some advocate making them more gender-typical, through therapy that reinforces such children for engaging in traditional gender-role activities so they will feel more compatible with same-sex peers (see, for example, Zucker, 2006). Others oppose this approach on grounds that it promotes a pathological view of gender atypicality, is likely to heighten felt pressure to conform (which predicts maladjustment), and—for children who fail to change—may result in parental rejection. These experts advocate modifying parents' and peers' attitudes, through interventions that help them become more accepting of children's gender-atypical interests and behaviors (Bigler, 2007; Conway, 2007; Crawford, 2003). **TAKE A MOMENT...** In view of what you have learned in this chapter, which approach do you think would be more successful, and why?

© JUPITERIMAGES/GETTY IMAGES/BRAND X PICTURES

For some young people, early adolescence is a time of gender intensification. Pubertal changes in appearance, traditional gender-role expectations of parents, and increased concern with what others think can prompt teenagers to move toward a more traditional gender identity.

Gender Identity in Adolescence

According to one hypothesis, the arrival of adolescence is typically accompanied by **gender intensification**—increased gender stereotyping of attitudes and behavior, and movement toward a more traditional gender identity (Hill & Lynch, 1983). Research on gender intensification, however, is mixed, with some studies finding evidence for it and others reporting few instances (Basow & Rubin, 1999; Galambos, Almeida, & Petersen, 1990; Huston & Alvarez, 1990; Priess, Lindberg, & Hyde, 2009). When gender intensification is evident, it seems to be stronger for adolescent girls. Although girls continue to be less gender-typed than boys, some may feel less free to experiment with "other-gender" activities and behaviors than they did in middle childhood.

In young people who do exhibit gender intensification, biological, social, and cognitive factors likely are involved. As puberty magnifies sex differences in appearance, teenagers may spend more time thinking about themselves in gender-linked ways.

Pubertal changes might also prompt gender-typed pressures from others. Parents with traditional gender-role beliefs may encourage "gender-appropriate" activities and behavior more than they did earlier (Crouter et al., 2007; Shanahan et al., 2007). And when adolescents start to date, they may become more gender-typed as a way of increasing their attractiveness (Maccoby, 1998). Finally, cognitive changes—in particular, greater concern with what others think—might make young teenagers more responsive to gender-role expectations.

Gender intensification typically declines by late adolescence, but not all affected young people move beyond it to the same degree. Some girls struggle with gender-typed social pressures to act in ways inconsistent with their actual beliefs, avoiding conflict by suppressing their honest thoughts and feelings (Tolman, 2002). In one study, eighth-grade girls who compromised their authenticity—by withholding their true opinions and emotions to avoid parental or peer disapproval—were less likely than their more authentic agemates to display the typical adolescent rise in self-esteem (see Chapter 11, page 462) (Impett et al., 2008).

Teenagers who are encouraged to explore non-gender-typed options and to question the value of gender stereotypes for themselves and their society are more likely to build an androgynous identity. Thus, the social environment is a major force in promoting gender-role flexibility in adolescence, just as it was at earlier ages.

Gender Schema Theory

Gender schema theory is an information-processing approach that explains how environmental pressures and children's cognitions work together to shape gender typing (Martin & Halverson, 1987; Martin, Ruble, & Szkrybalo, 2002). It also integrates the various elements of gender typing—gender stereotyping, gender identity, and gender-role adoption—into a unified picture of how masculine and feminine orientations emerge and are often strongly maintained.

At an early age, children pick up gender-stereotyped preferences and behaviors from others. At the same time, they organize their experiences into *gender schemas,* or masculine and feminine categories, that they use to interpret their world. As soon as preschoolers can label and appreciate the stability of their own gender, they select gender schemas consistent with it ("Only boys can be doctors" or "Cooking is a girl's job") and apply those categories to themselves. Their self-perceptions then become gender-typed and serve as additional schemas that children use to process information and guide their own behavior.

We have seen that individual differences exist in the extent to which children endorse gender-typed views. Figure 13.9 shows different cognitive pathways for children who often apply gender schemas to their experiences and those who rarely do (Liben & Bigler, 2002).

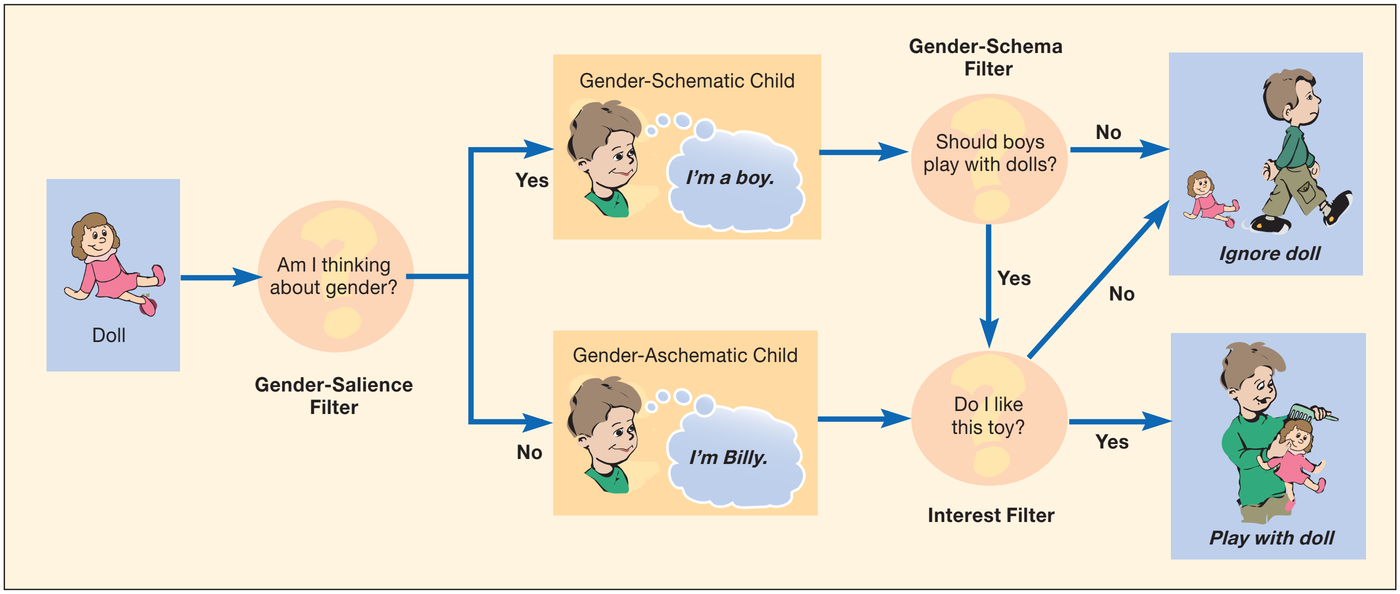


FIGURE 13.9 Cognitive pathways for gender-schematic and gender-aschematic children. In *gender-schematic children,* the gender-salience filter immediately makes gender highly relevant: Billy sees a doll and thinks, "I'm a boy. Should boys play with dolls?" Drawing on his experiences, he answers "yes" or "no." If he answers "yes" and the doll interests him, he plays with the doll. If he answers "no," he avoids the "gender-inappropriate" toy. *Gender-aschematic children* rarely view the world in gender-linked terms: Billy simply asks, "Do I like this toy?" and responds on the basis of his interests. (Reprinted by permission of Rebecca Bigler, University of Texas, Austin.)

© LAURA DWIGHT PHOTOGRAPHY

If working with clay were labeled "a girls' activity," would these third-grade boys continue modeling? If children believe a toy or game is for the other gender, powerful gender schemas lead them to like it less.

Consider Billy, who encounters a doll. If Billy is a *gender-schematic child,* his *gender-salience filter* immediately makes gender highly relevant. Drawing on his prior learning, he asks himself, "Should boys play with dolls?" If he answers "yes" and the toy interests him, he will approach it, explore it, and learn more about it. If he answers "no," he will respond by avoiding the "gender-inappropriate" toy. But if Billy is a *gender-aschematic child*—one who seldom views the world in gender-linked terms—he simply asks himself, "Do I like this toy?" and responds on the basis of his interests.

To examine the consequences of gender-schematic processing, researchers showed 4- and 5-year-olds "gender-neutral" toys that varied in attractiveness. An adult labeled some as boys' toys and others as girls' toys, leaving a third group unlabeled. Most children engaged in gender-schematic reasoning, preferring toys labeled for their gender and predicting that same-sex peers would also like those toys. Highly attractive toys, especially, lost their appeal when they were labeled as for the other gender (Martin, Eisenbud, & Rose, 1995). And because gender-schematic preschoolers typically conclude, "What I like, children of my own sex will also like," they often use their own preferences to add to their gender biases! For example, a girl who dislikes oysters may declare, "Only boys like oysters!" even though she has never actually been given information supporting such a stereotype (Liben & Bigler, 2002).

Gender-schematic thinking is so powerful that when children see others behaving in "gender-inconsistent" ways, they often cannot remember the behavior or distort their memory to make it "gender-consistent"—for example, when shown a picture of a male nurse, remembering him as a doctor (Liben & Signorella, 1993; Martin & Ruble, 2004). Over time, children learn much more about people, objects, and events that fit with their gender schemas than they do about "cross-gender" activities and behaviors.

Training school-age children in cognitive skills that counteract gender-biased social messages reduces their tendency to view the world in gender-schematic terms. When researchers taught 5- to 10-year-olds that ability and interest, not gender, determine whether a person can perform an activity well, children gained in stereotype flexibility and memory for "gender-inconsistent" information (story characters engaged in "cross-gender" tasks). Interestingly, classification training with gender-neutral stimuli that required children to sort objects into two categories at once (by shape and color) had the same effect (Bigler & Liben, 1992). As these findings reveal, interventions that promote multidimensional thinking about gender and other aspects of the world induce children to construct more gender-equitable beliefs. Nevertheless, gender-schematic thinking could not operate so forcefully to restrict knowledge and learning opportunities if society did not teach children a wide variety of gender-linked associations.

The Milestones table on the following page provides an overview of the changes in gender stereotyping, gender identity, and gender-role adoption we have considered.

ASK YOURSELF

Review ■ Describe the general path of gender identity development, from early childhood through adolescence, noting differences between boys and girls.

Connect ■ How might factors that affect identity development in general (see pages 472–474 in Chapter 11) influence gender identity in adolescence? Which influences would likely protect against gender intensification?

Apply ■ While looking at a book, 4-year-old Roger saw a picture of a boy cooking at a stove. Later, he recalled the person in the picture as a girl. Using gender schema theory, explain Roger's memory error.

Reflect ■ In early adolescence, did you and your friends display gender intensification? Describe examples. When did this concern with gender appropriateness decline?

Milestones

Gender Typing

AGE	GENDER STEREOTYPING AND GENDER-ROLE ADOPTION	GENDER IDENTITY
1–5 years	• Gender-stereotyped toy preferences emerge and strengthen. • Gender stereotyping of activities, occupations, and behaviors expands. • Gender segregation in peer interaction emerges and strengthens. • Girls' preference for play in pairs, boys' for play in larger groups, appears.	• Gender constancy develops in a three-stage sequence: gender labeling, gender stability, and gender consistency.
6–11 years	• Gender-stereotyped knowledge expands, especially for personality traits and achievement areas. • Gender stereotyping becomes more flexible.	• Among boys, "masculine" gender identity typically strengthens; girls' gender identity becomes more androgynous.
12–18 years	• Gender-role conformity may increase, followed by a decline. • Gender segregation becomes less pronounced.	• Gender identity may become more traditional, followed by a decline in stereotypical self-perceptions.

Note: These milestones represent overall age trends. Individual differences exist in the precise age at which each milestone is attained and in the extent of gender typing.

To What Extent Do Boys and Girls *Really* Differ in Gender-Stereotyped Attributes?

▶ Describe sex differences in mental abilities and personality traits, noting factors that contribute to those differences.

So far, we have examined the relationship of biological, social, and cognitive factors to children's gender-typed preferences and behavior. But we have said little about the extent to which boys and girls actually differ in mental abilities and personality traits. Over the past several decades, thousands of studies have measured sex differences in these characteristics. Researchers have looked for stable differences between males and females and, from there, have searched for biological and environmental contributions to each variation.

To avoid basing conclusions on single studies and small, potentially biased samples, researchers often use a technique called *meta-analysis,* in which they reanalyze the data of many investigations together. Besides telling us whether a sex difference exists, this method provides an estimate of its size. Table 13.2 on page 554 summarizes differences between boys and girls in mental abilities and personality traits, based on current evidence. The majority of findings listed in the table are small to moderate. Furthermore, the distributions for males and females usually overlap greatly. Sex differences typically account for no more than 5 to 10 percent of individual differences, leaving most to be explained by other factors. Consequently, males and females are actually more alike than different in developmental potential. Nevertheless, as we will see shortly, a few sex differences are considerable.

TABLE 13.2 Sex Differences in Mental Abilities and Personality Traits

CHARACTERISTIC	SEX DIFFERENCE
Verbal abilities	Girls are advantaged in early language development and in reading and writing achievement throughout the school years. On tests of verbal ability, girls outperform boys, more so when tests are heavily weighted with writing.
Spatial abilities	As early as infancy and persisting throughout the lifespan, boys outperform girls in certain spatial skills, with the largest differences appearing on tasks requiring mental rotation.
Mathematical abilities	In early childhood and the primary grades, girls are slightly advantaged in counting, arithmetic computation, and mastery of basic concepts. By late childhood and early adolescence, boys outperform girls on complex problems involving abstract reasoning and geometry and on math achievement tests. The difference is greatest among high-achieving students.
School performance	Girls get better grades than boys in all academic subjects throughout elementary and secondary school, including math and science. (Girls' advantage, however, does not extend to secondary school math and science achievement tests, which present complex problems not directly taught in school. See Mathematical abilities, above.)
Achievement motivation	Sex differences in achievement motivation are linked to type of task. Boys perceive themselves as more competent at and have higher expectancies for success in mathematics, science, sports, and mechanical skills. Girls have higher expectancies and set higher standards for themselves in reading, writing, literature, and art.
Emotional sensitivity	Girls score higher than boys in emotional understanding and on self-report measures of empathy and sympathy. Girls' advantage in prosocial behavior is greatest for kindness and considerateness, less apparent for helping behavior.
Fear, timidity, and anxiety	Girls are more fearful and timid than boys, a difference that is present in the first year of life. In school, girls are more anxious about failure and try harder to avoid it. Boys are greater risk takers, a difference reflected in their higher injury rates throughout childhood and adolescence.
Effortful control	Compared with boys, girls display greater effortful control, including capacity to inhibit impulses and shift attention away from irrelevant or emotionally arousing stimuli—traits that contribute to girls' better school performance and reduced incidence of behavior problems.
Compliance and dependency	Girls comply more readily with directives from adults and peers, in part because of their greater effortful control. They also seek help from adults more often and score higher in dependency on personality tests.
Activity level	Boys are more active than girls.
Depression	Adolescent girls are more likely than boys to report depressive symptoms.
Aggression	Boys are more physically aggressive than girls and, in adolescence, are far more likely to become involved in antisocial behavior and violent crime. The sex difference favoring girls in relational aggression is small.
Developmental problems	Problems more common among boys than girls include speech and language disorders, reading disabilities, and behavior problems such as hyperactivity, hostile acting-out behavior, and emotional and social immaturity. More boys are born with genetic disorders, physical disabilities, and mental retardation.

Mental Abilities

Sex differences in mental abilities have sparked almost as much controversy as the ethnic and SES differences in IQ considered in Chapter 8. Although boys and girls do not differ in general intelligence, they do vary in specific mental abilities. Many researchers, believing that heredity is involved in these disparities, have attempted to identify the biological processes responsible. But no biological factor operates in a social and cultural vacuum. For each ability we will consider, experience plays a considerable role.

Verbal Abilities Early in development, girls are slightly ahead of boys in language progress (see Chapter 9). Throughout the school years, girls attain higher scores in reading achievement and account for a lower percentage of children referred for remedial reading instruction. Girls continue to score slightly higher on tests of verbal ability in middle childhood and adolescence in every country in which assessments have been conducted (Bussiére, Knighton, & Pennock, 2007; Mullis et al., 2007; Wai et al., 2010). And when verbal tests are heavily weighted with writing, girls' advantage is large (Halpern et al., 2007).

A special concern is that girls' advantage in reading and writing achievement increases in adolescence, with boys doing especially poorly in writing—trends evident in the United States and other industrialized nations (see Figure 13.10) (OECD, 2010a; U.S. Department of Education, 2007, 2010). These differences in literacy skills are believed to be major contributors to a widening gender gap in college enrollments. Whereas 40 years ago, males accounted for 60 percent of U.S. undergraduate students, today they are in the minority, at 43 percent (U.S. Department of Education, 2011b).

Recall from Chapter 9 that girls have a biological advantage in earlier development of the left hemisphere of the cerebral cortex, where language is usually localized. And fMRI research indicates that in tackling language tasks (such as deciding whether two spoken or written words rhyme), 9- to 15-year-old girls show concentrated activity in language-specific brain areas. Boys, in contrast, display more widespread activation—in addition to language areas, considerable activity in auditory and visual areas, depending on how words are presented (Burman, Bitan, & Booth, 2007). This suggests that girls are more efficient language processors than boys, who rely heavily on sensory brain regions and process spoken and written words differently.

But girls also receive more verbal stimulation from the preschool years through adolescence, which may contribute to their more efficient processing (Peterson & Roberts, 2003). Furthermore, we have seen that children view language arts as a "feminine" subject. And, as noted in Chapter 8, as a result of the high-stakes testing movement, students today spend much time at their desks being taught in a regimented way—an approach particularly at odds with boys' higher activity level, assertiveness, and incidence of learning problems.

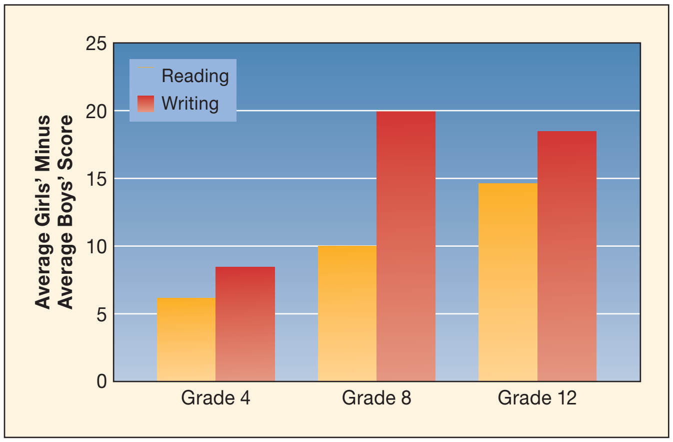

FIGURE 13.10 **Reading and writing achievement gaps favoring girls at grades 4, 8, and 12.** Findings are based on the U.S. National Assessment of Educational Progress. The bars represent the average girls' score minus the average boys' score. Thus, the height of the bar indicates the extent to which girls outperform boys, a difference that increases in adolescence. By grades 8 and 12, girls have an especially large advantage in writing skill. Similar trends are evident in other industrialized nations. (Adapted from U.S. Department of Education, 2007, 2010.)

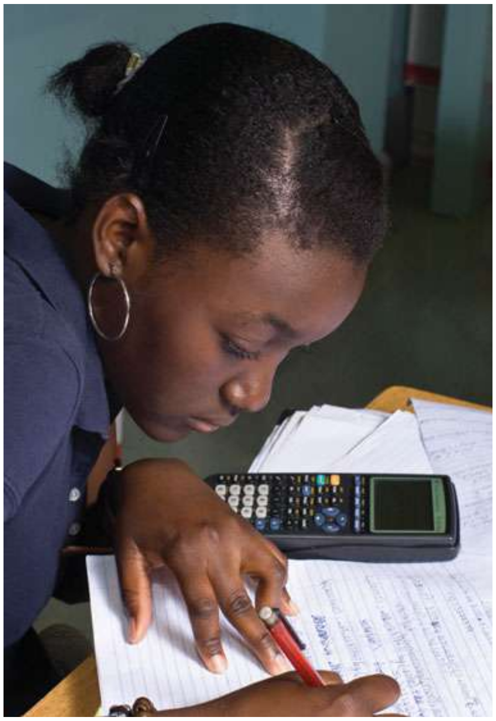
Finally, high rates of divorce and out-of-wedlock births mean that more children today grow up without the continuous presence of a father who models and encourages good work habits and skill at reading and writing. Both maternal and paternal involvement contributes to the achievement and educational attainment of young people of both sexes (Flouri & Buchanan, 2004). But some research suggests that high-achieving African-American boys are particularly likely to come from homes where fathers are warm, verbally communicative, and demanding of achievement (Grief, Hrabowski, & Maton, 1998). Clearly, reversing boys' weakening literacy skills is a high priority, requiring a concerted effort by families, schools, and supportive communities.

Mathematical Abilities

Studies of sex differences in mathematical abilities in early childhood and the primary grades are inconsistent. Some find no disparities, others slight differences depending on the math skill assessed (Lachance & Mazzocco, 2006). Girls tend to be advantaged in counting, arithmetic computation, and mastery of basic concepts, perhaps because of their better verbal skills and more methodical approach to problem solving. But by late childhood and early adolescence, when math concepts and problems become more abstract and spatial, boys outperform girls, with the difference especially evident on tests requiring complex reasoning and geometry (Bielinski & Davison, 1998; Gibbs, 2010; Lindberg et al., 2010). In science achievement, too, high school boys' advantage increases as problems become more difficult (Penner, 2003).

The male advantage is evident in most countries where males and females have equal access to secondary education. But the gap is typically small, varies considerably across nations, and has diminished over the past 30 years (Aud et al., 2011; Bussiére, Knighton, & Pennock, 2007; Halpern, Wai, & Saw, 2005; Lindberg et al., 2010; U.S. Department of Education, 2009). Among the most capable, however, the gender gap is greater. In widely publicized research on more than 100,000 bright seventh and eighth graders invited to take the Scholastic Assessment Test (SAT), boys outscored girls on



© LAURA DWIGHT PHOTOGRAPHY

As math problems become more abstract and spatial, boys outperform girls, especially among the most capable students. The gender gap is small, however, and has declined over the past generation.

BIOLOGY and ENVIRONMENT

Sex Differences in Spatial Abilities

Spatial skills are a key focus of researchers' efforts to explain sex differences in complex mathematical reasoning. The gender gap favoring males is large for *mental rotation tasks,* in which individuals must rotate a three-dimensional figure rapidly and accurately inside their heads (see Figure 13.11). Males also do considerably better on *spatial perception tasks,* in which people must determine spatial relationships by considering the orientation of the surrounding environment. Sex differences on *spatial visualization tasks,* involving analysis of complex visual forms, are weak or nonexistent. Because many different strategies can be used to solve these tasks, both sexes may come up with effective procedures (Collaer & Hill, 2006; Voyer, Voyer, & Bryden, 1995).

Sex differences in spatial skills emerge as early as the first few months of life, in male infants' superior ability to recognize a familiar object from a new perspective—a capacity requiring mental rotation (Moore & Johnson, 2008; Quinn & Liben, 2008). The male spatial advantage is present throughout childhood, adolescence, and adulthood in many cultures (Levine et al., 1999; Silverman, Choi, & Peters, 2007). The pattern is consistent enough to suggest a biological explanation. One hypothesis is that heredity, perhaps through prenatal exposure to androgen hormones, enhances right-hemispheric functioning, giving males a spatial

FIGURE 13.11 **Types of spatial tasks.** Large sex differences favoring males appear on mental rotation, and males do considerably better than females on spatial perception. In contrast, sex differences on spatial visualization are weak or nonexistent. (From M. C. Linn & A. C. Petersen, 1985, "Emergence and Characterization of Sex Differences in Spatial Ability: A Meta-Analysis," *Child Development, 56,* pp. 1482, 1483, 1485. © The Society for Research in Child Development. Reproduced with permission of Blackwell Publishing Ltd.)

the mathematics subtest year after year. Yet even this disparity has been shrinking. Thirty years ago, 13 times as many boys as girls scored over 700 (out of a possible 800) on the math portion of the SAT; today, the ratio is about 4 to 1 for seventh graders and 2 to 1 for high school students (Benbow & Stanley, 1983; Wai et al., 2010).

Some researchers believe that heredity contributes substantially to the gender gap in math, especially to the tendency for more boys to be extremely talented. Accumulating evidence indicates that boys' advantage originates in two skill areas: (1) their more rapid numerical memory, which permits them to devote more energy to complex mental operations; and (2) their superior spatial reasoning, which enhances their mathematical problem solving (Geary et al., 2000; Halpern et al., 2007). Indeed, 50 years of longitudinal evidence on nationally representative samples of U.S. high school students tracked for a decade or more reveals that consistently, high spatial ability in adolescence predicts subsequent advanced educational attainment in math-intensive fields and entry into science, technology, engineering, and math (STEM) careers, beyond the contribution of verbal and math ability (Wai, Lubinski, & Benbow, 2009). See the Biology and Environment box above for further consideration of this issue.

Social pressures are also influential. We have seen that many children view math as a "masculine" subject. Also, parents typically think boys are better at it—an attitude that encourages girls to view themselves as having to work harder at math to do well, to blame their errors on lack of ability, and to regard math as less useful for their future lives. These advantage. (Recall that for most people, spatial skills are housed in the right hemisphere of the cerebral cortex.) In support of this idea, girls and women whose prenatal androgen levels were abnormally high show superior performance on spatial rotation tasks (Berenbaum, 2001; Halpern & Collaer, 2005). Women with a male twin brother, who are exposed to slightly higher levels of prenatal androgens, outperform women with a female twin sister in spatial rotation (Heil et al., 2011; Vuoksimaa et al., 2010). In some studies, spatial performance varies with daily and annual androgen levels in both men and women (Temple & Carney, 1995; Van Goozen et al., 1995).

Why might a biologically based sex difference in spatial abilities exist? Evolutionary theorists point out that mental rotation skill predicts rapid, accurate map drawing and interpretation, areas in which boys and men do better than girls and women. Over the course of human evolution, the cognitive abilities of males became adapted for hunting, which required generating mental representations of large-scale spaces to find one's way (Jones, Braithwaite, & Healy, 2003). But this explanation is controversial. Critics point out that female gatherers also needed to travel long distances to find fruits and vegetables that ripened in different seasons (Newcombe, 2007).

Experience also contributes to males' superior spatial performance. Children who engage in manipulative activities, such as block play, model building, and carpentry, do better on spatial tasks (Baenninger & Newcombe, 1995). Furthermore, playing action video games enhances many cognitive processes important for spatial skills, including visual discrimination, speed of thinking, attention shifting, tracking of multiple objects, mental rotation, and wayfinding—gains that persist and generalize to diverse situations (Spence & Feng, 2010). Boys spend far more time than girls at these pursuits.

In studies of middle and high school students, *both* spatial ability and self-efficacy at doing math were related to performance on complex math problems, with spatial skills being the stronger predictor (Casey, Nuttall, & Pezaris, 1997, 2001). Boys are advantaged in both spatial abilities and math self-confidence. Still, spatial skills respond readily to training, with improvements often larger than the sex differences themselves. But because boys and girls show similar training effects, sex differences typically persist (Liu et al., 2008; Newcombe & Huttenlocher, 2006). In one study of first graders, however, training in mental rotation strategies over several months—a more intense approach than previously tried—led girls to reach the same performance level as boys (Tzuriel & Egozi, 2010). These findings suggest that the right kind of early intervention can override biologically based sex differences in spatial skills.

© BOB TORREZ/PHOTOEDIT

A gender gap favoring males exists for mental rotation tasks. But with intense training in mental rotation strategies, girls' performance improves markedly.

beliefs reduce girls' self-efficacy at doing math, which undermines their performance on math achievement tests and their willingness to consider STEM careers in college (Bhanot & Jovanovic, 2005; Bleeker & Jacobs, 2004; Kenney-Benson et al., 2006). In addition, *stereotype threat*—the fear of being judged on the basis of a negative stereotype (see page 341 in Chapter 8)—causes girls to do worse than their abilities allow on difficult math problems (Ben-Zeev et al., 2005; Muzzatti & Agnoli, 2007). As a result of all these influences, girls—even those who are highly talented—are less likely to develop effective math reasoning skills.

A positive sign is that today, American boys and girls reach advanced levels of high school math and science study in equal proportions—a crucial factor in reducing sex differences in knowledge and skill (Gallagher & Kaufman, 2005). Still, extra steps must be taken to promote girls' interest in and confidence at math and science. As Figure 13.12 on page 558 shows, in cultures that value gender equality, sex differences in secondary school students' math achievement are much smaller and, in one nation, reversed! Icelandic high school girls exceed boys in math scores (Guiso et al., 2008). Similarly, in countries where few individuals view science as "masculine," secondary school girls equal or exceed boys in science achievement (Nosek et al., 2009).

Furthermore, a math curriculum beginning in kindergarten that teaches children how to apply effective spatial strategies—drawing diagrams, mentally manipulating visual images, searching for numerical patterns, and graphing—is vital (Nuttall, Casey, & Pezaris, 2005). Because girls are biased toward verbal processing and perform less well than boys in spatial

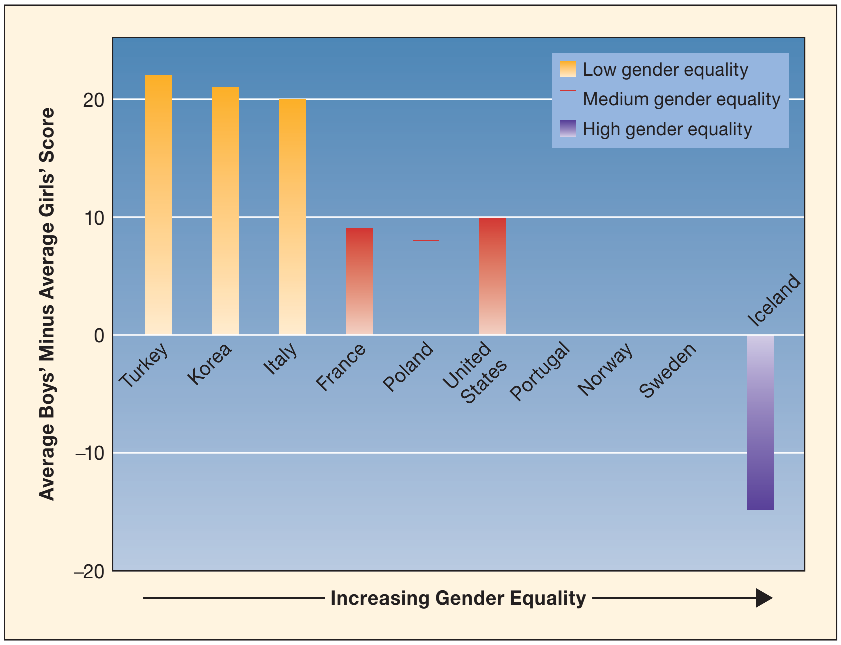

FIGURE 13.12 Math achievement gender gaps in 10 industrialized nations, arranged in order of increasing gender equality. Math achievement scores are based on 15-year-olds' performance on an identical test in each nation. Country gender equality is a composite measure that includes cultural attitudes toward women, women's participation in the labor force and in politics and government, and women's educational attainment and economic opportunities. As country gender equality increases, boys' advantage in math achievement declines; in Iceland, girls' math scores exceed boys'. (Adapted from Guiso et al., 2008.)

skills, they may not realize their math and science potential unless they are specifically taught how to think spatially.

Finally, role models of successful women are likely to add further to girls' interest and expectancies for success in advanced math and science courses and in STEM careers. The vastly greater presence of men in STEM fields—90 percent of engineers, 75 percent of math and computer occupations, 90 percent of physicists—is noticeable (U.S. Census Bureau, 2011b). In one study, female college science majors who viewed a video of a science conference depicting mostly males expressed a reduced sense of belonging, less desire to participate in the conference, and more neurobiological markers linked to stereotype threat (such as elevated heart rate and skin surface temperature) than their counterparts who watched a gender-balanced video (Murphy, Steele, & Gross, 2007). Exposure to women mathematicians, physical and computer scientists, and engineers might also help to convey how altruistic values, which are particularly important to girls and women (see page 543), can be fulfilled within STEM occupations.

Personality Traits

Sex differences in personality are in line with gender stereotypes. Traits most often studied include emotional sensitivity, depression, and aggression.

Emotional Sensitivity

Females are more emotionally sensitive than males, a difference that appears early. Beginning in the preschool years, girls perform slightly better when asked to infer others' emotional states and the causes of those states. Relative to boys, girls are especially adept at understanding the more complex, self-conscious emotions—an advantage that extends into adulthood (Bosacki & Moore, 2004; Brown & Dunn, 1996; Bybee, 1998). Except for anger, girls also express their feelings more freely and intensely in everyday interaction (Chaplin, Cole, & Zahn-Waxler, 2005; Geary, 1998). And girls are better at identifying their feelings. When researchers observed children's facial expressions of emotion as they watched emotionally arousing videotapes and then asked them how they felt, girls' verbal reports matched their expressed emotion far more often than boys' (Strayer & Roberts, 1997).

It would be reasonable to expect these differences in emotional sensitivity to extend to empathy, sympathy, and prosocial behavior, but the evidence is mixed. On self-report measures, girls and women score higher than boys and men. When they are observed for behavioral signs, however, the gender difference is less consistent. Girls show a slight advantage in prosocial responding that is mostly evident in kindness and considerateness, less apparent in helping behavior (Eisenberg & Fabes, 1998; Eisenberg, Fabes, & Spinrad, 2006). When asked to describe the prosocial acts of their peers, adolescents reported many as-yet-unstudied examples that require self-confidence and assertiveness and, therefore, might be especially common among boys (Bergin, Talley, & Hamer, 2003). These include helping others develop skills (giving tips on how to play basketball), providing physical assistance (volunteering to mow a neighbor's lawn), and confronting others for harmful or otherwise inappropriate behavior.

© DAVID YOUNG-WOLFF/PHOTOEDIT

As this affectionate big brother illustrates, young boys are not naturally less nurturant toward infants than girls. Gender differences in this aspect of emotional sensitivity develop in middle childhood, largely because of cultural expectations.

As with other attributes, both biological and environmental explanations for sex differences in emotional sensitivity exist. According to one evolutionary account, females are genetically primed to be more emotionally sensitive as a way of ensuring their effectiveness as caregivers. Yet research suggests that girls are not naturally more nurturant. Before age 5, boys and girls spend equal amounts of time talking to and playing with babies (Fogel et al., 1987). In middle childhood, Caucasian boys' willingness to relate to infants declines. Yet African-American school-age boys, who endorse fewer gender stereotypes, smile, touch, and look at babies just as much as girls do (Reid & Trotter, 1993). Also, sex differences in emotional sensitivity are not evident in mothers' and fathers' interactions with their babies. In Chapter 10, we saw that fathers are just as affectionate and competent at caregiving as mothers. And in Chapter 4, we noted that men and women react similarly to the sound of a crying baby.

Cultural expectations that girls be warm and expressive and boys be distant and self-controlled seem largely responsible for the gender gap in emotional sensitivity. In infancy, mothers respond more often to a girl's happiness and distress than to a boy's (Malatesta et al., 1986). Similarly, during the preschool years, both fathers and mothers attend more to girls' than boys' sadness and anxiety, and this parental attentiveness predicts greater expression of these emotions by children two years later (Chaplin, Cole, & Zahn-Waxler, 2005). Also, parents are more likely to use inductive discipline (which promotes sympathetic concern) with girls and to pressure girls to be thoughtful and caring (Zahn-Waxler, Cole, & Barrett, 1991). Finally, recall that parents spend more time talking about emotions when conversing with daughters. Taken together, these findings suggest that girls receive far more encouragement than boys to express and reflect on feelings.

Depression Depression—feeling sad, frustrated, and hopeless about life, accompanied by loss of pleasure in most activities and disturbances in sleep, appetite, concentration, and energy—is the most common psychological problem of adolescence. Among U.S. teenagers, 20 to 50 percent experience mild to moderate feelings of depression, bouncing back after a short time. More worrisome are the 15 to 20 percent who have had one or more major depressive episodes, a rate comparable to that of adults. From 2 to 8 percent are chronically depressed—gloomy and self-critical for many months and sometimes years (Graber & Sontag, 2009; Rushton, Forcier, & Schectman, 2002).

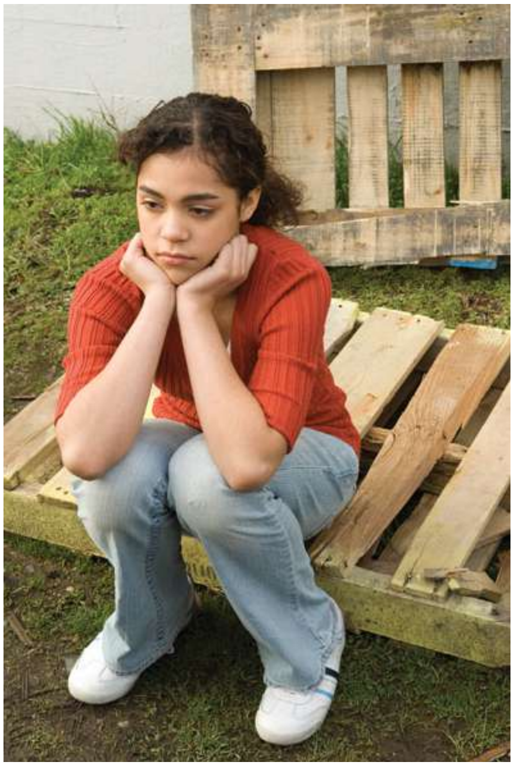
Serious depression affects only 1 to 2 percent of children, many of whom (especially girls) remain depressed in adolescence. In addition, depression increases sharply from ages 12 to 16 in industrialized nations, with many more girls than boys displaying adolescent onset of symptoms. Teenage girls are twice as likely as boys to report persistent depressed mood—a sex difference sustained throughout the lifespan (Dekker et al., 2007; Hankin & Abela, 2005; Nolen-Hoeksema, 2002). If allowed to continue, depression seriously impairs social, academic, and vocational functioning.

The precise combination of biological and environmental factors leading to depression varies from one individual to the next. Kinship studies reveal that heredity plays an important role (Glowinski et al., 2003). Genes can induce depression by affecting the balance of neurotransmitters in the brain, the development of brain regions involved in inhibiting negative emotion, or the body's hormonal response to stress (Kaufman & Charney, 2003).

But experience can also activate depression, promoting any of these biological changes. Parents of depressed children and adolescents show a high incidence of depression and other psychological disorders. Although a genetic risk may be passed from parent to child, in earlier chapters we saw that depressed or otherwise stressed parents often form insecure attachments with their children and engage in maladaptive parenting. As a result, their child's emotional self-regulation, attachment, and self-esteem may be impaired, with serious consequences for many cognitive and social skills (Abela et al., 2005; Yap, Allen, & Ladouceur, 2008). Depressed youths usually display a learned-helpless attributional style, viewing positive academic and social outcomes as beyond their control (Graber, 2004). In a vulnerable young person, numerous negative life events can spark depression—for example, failing at something important, parental divorce, the end of a close friendship or romantic partnership, or the challenges of school transition.

Why are girls more prone to depression than boys? Biological changes associated with puberty cannot be a major factor because the gender difference is limited to industrialized nations. In developing countries, rates of depression are similar for males and females and occasionally higher in males (Culbertson, 1997). Even when females do exceed males in depression, the size of the difference varies. For example, it is smaller in China than in the United States, perhaps because of decades of efforts by the Chinese government to eliminate gender inequalities (Greenberger et al., 2000).

Instead, stressful life events and gender-typed coping styles seem to be responsible. Early-maturing girls are especially prone to depression, particularly when they also face other stressful life events (see Chapter 5). And adolescent gender intensification may strengthen girls' passivity, dependency, and tendency to ruminate on (repetitively mull over) their anxieties and problems—maladaptive approaches to tasks expected of teenagers in complex cultures. Consistent with this explanation, adolescents who identify strongly with "feminine" traits ruminate more and tend to be more depressed, regardless of their sex (Lopez, Driscoll, & Kistner, 2009; Papadakis et al., 2006). Girls who repeatedly feel overwhelmed develop an overly reactive physiological stress response and cope more poorly with challenges in the future (Hyde, Mezulis, & Abramson, 2008; Nolen-Hoeksema, 2006). In this way, stressful experiences and stress reactivity feed on one another, sustaining depression. In contrast, girls with either an androgynous or a "masculine" gender identity show low rates of depressive symptoms (Priess, Lindberg, & Hyde, 2009; Wilson & Cairns, 1988).



© ELKE VAN DE VELDE/GETTY IMAGES/BRAND X PICTURES

In industrialized nations, stressful life events and gender-typed coping styles—passivity, dependency, and rumination—make adolescent girls more prone to depression than boys.

Unfortunately, the stereotypical view of adolescence as a period of "storm and stress" leads many adults to minimize the seriousness of adolescents' depression, misinterpreting it as just a passing phase. As a result, the overwhelming majority of depressed teenagers do not receive treatment (Asarnow et al., 2005). Yet without intervention that improves coping strategies and reduces high reactivity to stress, adolescent depression is likely to evolve into a lifelong pattern.

Aggression Aggression has attracted more research attention than any other sex difference. In Chapter 12, we noted that by the second year, boys are more *physically aggressive* than girls. But sex differences in *verbal aggression* (threats of physical harm, name-calling, and hostile teasing) and *relational aggression* (aimed at damaging another's social relationships) are minimal. A common but inaccurate assumption is that the rumor spreading, social exclusion, and other types of relationship manipulation that make up relational aggression are considerably more common in girls. But girls exceed boys only slightly (Crick et al., 2004, 2006; Crick, Ostrov, & Werner, 2006). Girls often *appear* much more relationally aggressive than boys because many girls use relational tactics nearly exclusively. Boys, by contrast, draw on a diversity of means to inflict harm—whatever works at the moment.

Although children of both sexes find relational aggression to be very hurtful, girls find it especially so, reporting more distress and judging it to be more unjust than boys do (Galen & Underwood, 1997; Murray-Close, Crick, & Galotti, 2006). Because girls place a high value on close relationships, harming a friendship is a powerful way to hurt a peer. There are other reasons, too, that relational aggression accounts for the large majority of girls' hostile acts. First, girls spend more time in close proximity to adults and are more sensitive to adult approval. They may emphasize relational aggression because it is hard for adults to detect and, therefore, to punish. Second, as Chapter 15 will make clear, dominance relations are less clear in girls' than in boys' peer groups. As a result, girls may jockey for social position frequently, engaging in relationship manipulation to protect their own status (Underwood, 2003).

Our discussion of the origins of sex differences in aggression focuses on physical aggression. At present, much less is known about factors that contribute to relational aggression.

Biological Influences. Because males' greater physical aggression is evident early in life, generalizes across cultures, and is found in many animal species, most researchers believe that biology is involved. Androgen hormones are related to aggression in animals and are also believed to play a role in humans. But children with CAH, who were exposed prenatally to abnormally high androgen levels, are not consistently more aggressive (Berenbaum & Resnick, 1997; Mathews et al., 2009). Perhaps androgens promote certain behaviors that, in some circumstances, increase the likelihood of aggressive outcomes.

One possibility is that prenatal androgens promote physical activity and competitiveness—behaviors likely to change into aggression in certain situations (Dodge, Coie, & Lynam, 2006). For example, an active, competitive child who often participates in large-group activities might become more aggressive than a child who prefers small-group pursuits. To explore this idea, researchers brought kindergartners and first graders to a laboratory where they played a game, some in same-sex pairs and others in same-sex tetrads (groups of four). In the game, children rolled a die, which indicated how many beads they could take from either a common pile (a noncompetitive move) or another player (a competitive move). Group size had no impact on girls' competitive moves, but boys displayed nearly twice as many competitive moves in tetrads as in dyads (Benenson et al., 2001). Recall that compared with girls, boys spend more time playing in large groups—an attraction, according to evolutionary theorists, adapted to preparing them for the competitive adult life of their male ancestors. Large groups, in turn, serve as contexts in which competition and striving for social dominance may promote aggression.

© ELLEN B. SENISI PHOTOGRAPHY

The sex difference favoring girls in relational aggression is small. But because girls place a high value on close relationships, they find relational tactics especially hurtful.

Another hypothesis is that sex hormones influence brain functioning in ways that affect emotional reactions. According to this view, hormone levels induce more frequent displays of excitement, anger, or anxiety, which make aggression more likely under certain conditions. Consistent with this prediction, adolescent boys with high androgen levels are more dominant and, therefore, more likely to respond with aggression when provoked by peers (Olweus et al., 1988; Tremblay et al., 1997). In one study, higher estrogen and androgen levels were related to adolescent girls' expressions of anger in a discussion session with their parents (Inoff-Germain et al., 1988).

Although more research is needed, current evidence indicates that multiple pathways exist between sex hormones and physical aggression. Clearly, too, environmental conditions have much to do with whether or not hormonally induced emotions and behaviors are channeled into aggressive acts.

Environmental Influences. In Chapter 12, we showed how coercive child-rearing practices promote aggressive behavior. Boys are more likely than girls to be affected because parents more often use physical punishment with boys, which encourages them to adopt the same tactics in their own relationships (Hester, He, & Tian, 2009; Sobring, Rodholm-Funnemark, & Palmerus, 2003).

At the same time, parents and teachers respond differently to boys' and girls' physical aggression. They often give boys positive attention or relax rules, coaxing, begging, or ignoring rather than using clear, firm prohibitions. In contrast, they usually respond negatively to girls' assertive and aggressive acts (Arnold, McWilliams, & Harvey-Arnold, 1998; Kerig, Cowan, & Cowan, 1993; Radke-Yarrow & Kochanska, 1990). The stereotypical view that "boys will be boys" may lead many adults to overlook or tolerate boys' hostility unless it is extreme, so that boys receive tacit approval for physical aggression, whereas girls suppress it.

LOOK and LISTEN

Ask several adolescents to describe instances they witnessed in which boys and girls engaged in relational aggression ("were mean to a peer"). Then ask why these behaviors occur and their likely emotional impact. Are participants' responses consistent with evidence on sex differences in relational aggression?

It is not surprising, then, that school-age boys expect less parental disapproval and report feeling less guilty for aggression than girls (Perry, Perry, & Weiss, 1989).

Gender-segregated peer groups extend adults' lessons about expressing aggression, with boys often engaging in high rates of bossy, rough, aggressive acts while girls encourage one another to refrain from physical fighting. In one study, emotionally reactive preschool and kindergarten boys who mostly played with other boys showed an increase in teacher-reported problem behaviors ("starts fights," "is defiant to adults") over the school year. Among emotionally reactive girls who often played with other girls, problem behaviors decreased (Fabes et al., 1997). Perhaps these girls begin to vent their anger indirectly. By middle childhood, girls' relational aggression is more malicious than boys' and more likely to be directed at close friends (Pronk & Zimmer-Gembeck, 2010; Rose & Rudolph, 2006). Boys, in contrast, more often use relational aggression to exclude peers from large groups because of poor athletic skill, perceived "feminine" identity, or physical weakness.

In sum, early experiences tend to promote physical aggression in boys but to dampen it in girls, encouraging them to find covert, relational outlets for their hostility. Overall, biological predispositions and social encouragement jointly contribute to sex differences in aggression.

© TED FOXX/ALAMY IMAGES

In gender-segregated peer groups, boys and girls express aggression in different ways. Boys more often engage in bossy, rough aggressive acts.

Developing Non-Gender-Stereotyped Children

▶ Cite ways to reduce gender stereotyping in children.

We have seen that children's developmental possibilities can be seriously limited by persistent gender stereotypes in their culture. Despite wide recognition of the importance of rearing children who feel free to express their human qualities without fear of violating gender-role expectations, no easy recipe exists for accomplishing this difficult task. It must be tackled on many fronts—at home, at school, and in the wider society.

Biology clearly affects children's gender typing, channeling boys toward active, competitive play and girls toward quieter, more intimate interaction—a difference that leads each sex, on average, to seek out activities and social experiences consistent with those predispositions. But substantial revisions in gender roles and in relationships between males and females—along with wide individual, family, and cultural variations—reveal that most aspects of gender typing are not built into human nature (Maccoby, 2000b). Furthermore, a long human childhood ensures that experiences can greatly influence biologically based sex differences (Ruble, Martin, & Berenbaum, 2006).

Throughout our discussion, we have mentioned strategies for reducing gender stereotyping and gender-role conformity. These are summarized in Applying What We Know on the following page. But even children fortunate enough to grow up in homes and schools that minimize stereotyping will eventually encounter it in the media and in the typical roles of men and women in their communities. Consequently, children need early experiences that repeatedly counteract their readiness to absorb our culture's extensive network of gender-linked associations.

Because preschoolers' cognitive limitations lead them to assume that cultural practices determine gender, Sandra Bem (1993, 1998) suggests that parents and teachers make a concerted effort to delay young children's learning of gender-stereotyped messages. Adults can begin by eliminating traditional gender roles from their own behavior and from the alternatives they provide for children. For example, mothers and fathers can take turns making dinner, bathing children, and driving the family car and can provide sons and daughters with both trucks and dolls, both pink and blue clothing. Teachers can make sure that all

APPLYING WHAT WE KNOW

Reducing Children's Gender Stereotyping and Gender-Role Conformity

STRATEGY	EXPLANATION
Permit children to choose among diverse toys and activities.	Encouraging children to select toys and activities on the basis of their interests, not "gender appropriateness," counters gender stereotypes and gives children a broader array of experiences.
Avoid transmitting gender stereotypes of achievement areas; point out that high effort improves competence in all areas.	Avoiding gender stereotypes about what boys and girls are "good at" encourages children's sense of competence at, interest in, and motivation to achieve in areas stereotyped for the other gender, thereby enabling them to realize their academic potential.
Teach children to appreciate differences among individuals.	Emphasizing individual differences (for example, one woman saying about another, "She's so interesting because she's different from me!") reduces the pressure children feel to adopt stereotypical attitudes and behaviors associated with their own gender.
Avoid unnecessary references to gender and gender stereotypes in your language.	Avoiding gender labels and generic utterances ("The boys aren't paying attention." "Most girls like art.") by referring, instead, to individuals ("Mark, Sam, and Jenny aren't paying attention." "Susie likes art.") prevents children from viewing same-sex individuals as alike and from accepting gender stereotypes.
Provide non-gender-stereotyped models.	Exposure to adults engaged in nonstereotyped activities and occupations promotes children's awareness that multiple choices are available to them.
Stress the complexity of gender groups.	Comments like "Some boys are good at math, and some girls are good at math," or "Some boys like sports, and some boys don't like sports," teach children that ability and interest, not gender, determine individual performance.
Arrange for mixed-sex interaction.	Children who have opportunities to engage in joint endeavors with other-sex peers are less likely to form gender stereotypes.
Discuss gender biases with children.	Discussing why certain social roles (such as president) are typically linked to one gender helps children to appreciate environmental causes of bias and to reject explanations based on innate sex differences.

children spend some time each day in both adult-structured and unstructured activities. Adults can also avoid using language that conveys gender stereotypes and can shield children from media presentations that do the same.

Once children notice the wide array of gender stereotypes in their society, parents and teachers can point out exceptions. For example, they can arrange for children to see men and women pursuing nontraditional careers and can explain that interests and skills, not sex, should determine a person's occupation. With older children, adults can discuss the historical roots and current consequences of gender inequalities—why, for example, there has not yet been a female U.S. president, why fathers rarely stay home with young children, and why stereotyped views of men and women are hard to change. In addition, Bem (1983) suggests providing children with a "sexism schema"—a knowledge framework for processing gender stereotypes and prejudice that triggers moral indignation. In this way, children can participate in promoting positive social change. (For an illustration, return to the Social Issues: Education box on page 545, in which children were taught to recognize and confront peers' sexist remarks.)

Research shows that school-age children who hold flexible beliefs about what boys and girls can do are more likely to notice instances of gender discrimination (Brown & Bigler, 2004). As children build concepts of themselves and their social world that are not limited by a masculine–feminine dichotomy, they contribute to the transformation of societal values, bringing us closer to a time when people will be released from the constraints of traditional gender roles.

ASK YOURSELF

Review ■ Cite evidence that both biological and environmental factors contribute to girls' advantage in verbal abilities and to boys' advantage in mathematical reasoning.

Review ■ Explain possible *indirect* links between androgen hormones and boys' greater physical aggression, noting the influence of both family and peer-group experiences.

Connect ■ Using Bronfenbrenner's ecological systems theory (see Chapter 1, page 26), describe steps that can be taken at each level of the environment to reduce gender stereotyping in children.

Apply ■ Thirteen-year-old Donna, who has a "feminine" gender identity, reached puberty early, is dissatisfied with her physical appearance, and often ruminates about how well her peers like her. Explain why Donna is at risk for depression.

SUMMARY

Explain how the study of gender typing has responded to societal change.

- Largely because of progress in women's rights, **gender typing** is no longer regarded as essential for healthy adjustment. Current research focuses on how biological, cognitive, and social factors influence development of **gender stereotypes**, **gender roles,** and **gender identity,** and on how to free children from gender-based societal expectations.

Gender Stereotypes and Gender Roles (p. 530)

Describe the development of gender stereotyping from early childhood into adolescence.

- Children begin acquiring gender stereotypes early in the preschool years. By middle childhood, they are aware of stereotypes for activities, behaviors, occupations, achievement areas, and—for personality—**instrumental** and **expressive traits.** Gains in **gender-stereotype flexibility** occur in middle childhood and adolescence, but children still may disapprove of violations of gender-role expectations, especially by males.

Cite individual and group differences in gender stereotyping, and discuss the relationship between gender stereotyping and gender-role adoption.

- Children acquire gender stereotypes in idiosyncratic ways, yielding wide individual differences. Boys hold more rigid gender-stereotyped views than girls, white children more than black children. Higher-SES adolescents and adults hold more flexible views than their lower-SES counterparts.
- Awareness of gender stereotypes is only weakly related to gender-role adoption. Stereotype flexibility, however, is a good predictor of school-age children's willingness to cross gender lines.

Influences on Gender Stereotyping and Gender-Role Adoption (p. 535)

Discuss biological influences on gender stereotyping and gender-role adoption.

- According to an evolutionary perspective, males are genetically primed for dominance and females for intimacy, responsiveness, and cooperation. Cross-cultural similarities in gender typing have been found, but cultures vary widely in the extent to which they promote gender-role conformity.

© RAFIQUR RAHMAN/REUTERS/CORBIS

- Prenatal androgen levels contribute to sex differences in play styles and to preference for same-sex peers. Research on children with congenital adrenal hyperplasia (CAH) and androgen insensitivity syndrome supports the role of androgens in "masculine" gender-role adoption.

Discuss environmental influences on gender stereotyping and gender-role adoption.

- Beginning in infancy, adults hold gender-stereotyped perceptions and expectations of children. Early on, parents reinforce "gender-appropriate" play activities and behaviors and often use language that highlights gender distinctions.
- In middle childhood, parents demand higher achievement from boys and hold gender-stereotyped beliefs about children's academic abilities, with consequences for achievement and career choices. Fathers tend to differentiate between boys and girls more than mothers.
- Teachers reinforce children of both sexes for "feminine" behavior while also promoting traditional gender roles. Children also learn through observation of gender-typed models in the surrounding environment.
- Interaction with same-sex peers further reinforces children's "gender-appropriate" activity choices and promotes gender-typed styles of social influence.
- The impact of siblings on gender typing varies with birth order and family size. In larger families, same-sex siblings often strive to be different from one another and are likely to be less stereotyped.

Gender Identity (p. 547)

Discuss androgyny as well as social learning and cognitive-developmental views of the development of gender identity in early childhood.

- Although most people have a traditional gender identity, a substantial minority are **androgynous,** combing both masculine and feminine characteristics. Masculine and androgynous identities are linked to better psychological adjustment.

- According to social learning theory, preschoolers first acquire gender-typed responses through modeling and reinforcement and then organize these into gender-linked ideas about themselves. Cognitive-developmental theory suggests that **gender constancy** must precede gender-typed behavior.
- Children master gender constancy in three stages: **gender labeling**, **gender stability,** and **gender consistency.** Contrary to cognitive-developmental predictions, "gender-appropriate" behavior is acquired long before gender constancy. Whereas gender labeling and gender stability strengthen early gender-role adoption, gender consistency seems to contribute to gender-stereotype flexibility.

© SALLY AND RICHARD GREENHILL/ALAMY IMAGES

What changes in gender identity occur in middle childhood and adolescence?

- In middle childhood, boys strengthen their identification with the "masculine" role, while girls become more androgynous. Gender identity includes self-evaluations of gender typicality, contentedness, and felt pressure to conform to gender roles—each of which affects adjustment.
- Some research suggests that early adolescence is a period of **gender intensification,** in which gender stereotyping of attitudes and behavior increases, though evidence is mixed.

Explain gender schema theory.

- **Gender schema theory** is an information-processing approach that explains how environmental pressures and children's cognitions jointly shape gender typing. As children learn gender-stereotyped preferences and behaviors, they form masculine and feminine gender schemas that they apply to themselves and their worlds. Highly gender-schematic children view themselves and their surroundings in gender-linked terms and, as a result, learn more about "gender-appropriate" than "gender-inappropriate" activities and behaviors.

To What Extent Do Boys and Girls *Really* Differ in Gender-Stereotyped Attributes? (p. 553)

Describe sex differences in mental abilities and personality traits, noting factors that contribute to those differences.

- Most sex differences in mental abilities and personality traits are small to moderate. Girls tend to be advantaged in language development, reading and writing, counting, arithmetic computation, mastery of basic math concepts, and emotional understanding. Boys are better at certain spatial skills and at complex mathematical reasoning.
- Biological factors, adult encouragement, and learning opportunities contribute to sex differences in language, spatial, and math skills. Girls' greater emotional sensitivity is largely due to gender-stereotyped expectations and child-rearing practices.
- The higher rate of depression in adolescent girls in industrialized nations largely results from stressful life events and gender-typed coping styles. Gender intensification in early adolescence may strengthen girls' passivity and dependency, which interfere with their ability to cope with challenges.

© ELKE VAN DE VELDE/GETTY IMAGES/BRAND X PICTURES

- Androgen hormones contribute to greater physical aggression in males but may exert their effects indirectly by influencing activity level, emotional reactions, or dominance. Parents and teachers are more likely to encourage physical aggression in boys while suppressing it in girls—lessons reinforced by gender-segregated peer groups.

Developing Non-Gender-Stereotyped Children (p. 562)

Cite ways to reduce gender stereotyping in children.

- Parents and teachers can counteract young children's readiness to absorb gender-linked associations by eliminating traditional gender roles from their own behavior. Once children notice gender stereotypes, adults can point out exceptions and discuss the arbitrariness of many gender inequalities.

CHAPTER 14

“Untitled”

Anagha, 12 years, Kuwait

Of all contexts influencing children’s development, the family is the most powerful. This depiction of parents and child strolling in a tranquil wintry landscape evokes the sense of safety and security that the family provides.

Reprinted with permission from the International Museum of Children’s Art, Oslo, Norway

The Family

"I don't remember much family togetherness when I was a kid," 19-year-old Hannah reflected over dinner with Aunt Eva and Uncle Charlie. "Our parents couldn't talk things out with each other, and they weren't very open with us. We almost never sat down to a meal or went anywhere together. I joined Girl Scouts and went to summer camp. I liked the activities and made good friends, but they couldn't make up for the absence of warm family time."

When Hannah was 9, her parents divorced, and she moved across the country with her mother. At first, her father arranged visits every few months, taking Hannah out to eat and to the movies and buying her whatever she asked for. Back home, when Hannah objected to her mother's rules and demands, her mother would rail at her father, calling him a "Disneyland Dad" who took no serious responsibility for Hannah's upbringing. As these arguments flared repeatedly, visits from Hannah's father trailed off.

To make ends meet, Hannah's mother extended her work hours to evenings and weekends. Hannah would make a box of macaroni and cheese for dinner, eat by herself, and then—neglecting her homework—spend hours watching TV, texting her friends, or just daydreaming. She found it hard to concentrate, and her grades suffered. In high school, stormy relationships with boyfriends left Hannah feeling depressed and rejected. Aimless and "at sea," she was convinced she couldn't do anything.

At 17, Hannah got her driver's license. Longing for a sense of family togetherness, she began making repeated visits to her Aunt Eva and Uncle Charlie, who lived in a neighboring city. They listened to Hannah, encouraged her, and helped her with time management, academic, and relationship problems. Two years later, when Hannah graduated from high school with plans to enter a university, she attributed her turnabout in motivation and self-confidence to her aunt and uncle's warmth, involvement, and guidance.

The family is the child's first, and longest-lasting, context for development. Compared with other species, human children develop slowly, requiring years of protection, support, and teaching before they are ready to be independent. This gradual journey to maturity has left an imprint on human social organization everywhere: Families are pervasive, and parenting is universally important in children's lives. Children who lack a satisfying, supportive family life are likely to crave it. Some, like Hannah, find what they seek in extended family or another special adult.

Of course, other contexts also mold children's development, but none equals the family in power and breadth of influence. The attachments children form with parents and siblings usually last a lifetime and serve as models for relationships in the wider world of neighborhood and school. Within the family, children experience their first social conflicts. Discipline by parents and arguments with siblings provide important lessons in compliance and cooperation and opportunities to learn how to influence others. Finally, within the family, children learn the language, skills, and social and moral values of their culture.

We begin our discussion by examining why this social unit came into being and has survived for thousands of years. Then we describe the current view of the family as a *social system* with many interacting influences on the child. Next, we look closely at the family as the core socializing agency of society by considering child-rearing styles, factors that influence them, and their consequences for children's development. We also address recent social changes that have led to great diversity in family lifestyles. Finally, recognizing that the contemporary family is especially vulnerable to a breakdown in protective, emotionally supportive parent–child relationships, we consider the origins and consequences of child maltreatment. ■

- Discuss evolutionary origins of the family, and cite functions contemporary families perform for society.

Origins and Functions of the Family

The family in its most common form—an enduring commitment between a man and a woman who feed, shelter, and nurture their children until they reach maturity—arose tens of thousands of years ago among our hunting-and-gathering ancestors. From an evolutionary perspective, the human family enhanced survival by ensuring a relatively even balance of male hunters and female gatherers within a social group, thereby providing protection against starvation at times when game was scarce (Lancaster & Whitten, 1980).

An extended relationship between a man and a woman also increased male certainty that a newborn baby was actually *his* offspring, motivating him to care and provide for mother and child and to invest in child rearing in order to increase the odds of child survival (Bjorklund, Yunger, & Pellegrini, 2002; Geary, 2000). Larger kin networks that included grandparents, aunts, uncles, and cousins formed, increasing the chances of successful competition with other humans for vital resources and providing assistance with child rearing.

Besides promoting survival of its members, the family unit of our evolutionary ancestors performed the following vital services for society:

- *Reproduction.* Replacing dying members.
- *Economic services.* Producing and distributing goods and services.
- *Social order.* Devising procedures for reducing conflict and maintaining order.
- *Socialization.* Training the young to become competent, participating members of society.
- *Emotional support.* Helping others surmount emotional crises and fostering in each person a sense of commitment and purpose.

As societies became more complex, the demands placed on the family became too much for it to sustain alone. Other institutions developed to assist with some of these functions, and families became linked to larger social structures (Parke & Kellam, 1994). For example, political and legal institutions assumed responsibility for ensuring societal order, and schools and religious institutions extended the family's socialization function. And although some family members still carry out economic tasks together (as in family-run farms and businesses), this function has largely been taken over by institutions that make up the world of work.

Despite sharing some functions with other institutions, the family continues to assume primary responsibility for three important ones especially concerned with children: reproduction, socialization, and emotional support. Researchers interested in finding out how families fulfill these functions take a **social systems perspective,** viewing the family as a complex set of interacting relationships influenced by the larger social context.

The most common family structure—the nuclear family—arose tens of thousands of years ago because it enhanced survival. *Left photo:* A Mexican family cooks a meal at a market that provides individual barbecue grills. *Right photo:* A Chinese-American family celebrates Chinese New Year in New York.

The Family as a Social System

▶ Describe the social systems perspective on family functioning.

The social systems perspective on family functioning grew out of researchers' efforts to describe and explain the complex patterns of interaction between family members. As you will see, it has much in common with Bronfenbrenner's *ecological systems theory,* discussed in Chapter 1. Family systems theorists recognize that parents do not mechanically shape their children. Rather, as you already know from earlier chapters, *bidirectional influences* exist, whereby family members mutually influence one another. The very term *family system* implies a network of interdependent relationships (Bornstein & Sawyer, 2006; Bronfenbrenner & Morris, 2006; Parke & Buriel, 2006). These system influences operate both directly and indirectly.

Direct Influences

Recently, as I passed through the checkout counter at the supermarket, I witnessed two episodes, each an example of how parents and children directly influence each other:

- Four-year-old Danny looked longingly at the tempting rows of candy as his mother lifted groceries from her cart onto the counter. "Pleeeease, can I have it, Mom?" Danny begged, holding up a package of bubble gum. "Do you have a dollar? Just one?"

  "No, not today," his mother answered. "Remember, we picked out your special cereal. That's what I need the dollar for." Gently taking the bubble gum from his hand, Danny's mother handed him the box of cereal. "Here, let's pay," she said, lifting Danny so he could see the checkout counter.
- Three-year-old Meg sat in the shopping cart while her mother transferred groceries to the counter. Suddenly Meg turned around, grabbed a bunch of bananas, and started pulling them apart.

  "Stop it, Meg!" shouted her mother, snatching the bananas from Meg's hand. But as she turned her attention to swiping her debit card, Meg reached for a chocolate bar from a nearby display. "Meg, how many times have I told you, *don't touch!*" Prying the candy from Meg's tight little fist, Meg's mother slapped her hand. Meg's face turned red with anger as she began to wail.

These observations fit with a wealth of research on the family system. Studies of families of diverse ethnicities show that when parents are firm but warm (like Danny's mother), children tend to comply with their requests. And when children cooperate, their parents are likely to be warm and gentle in the future. In contrast, parents who discipline with harshness and impatience (like Meg's mother) tend to have children who resist and rebel. Because children's misbehavior is stressful for parents, they may increase their use of punishment, leading to more unruliness by the child (Stormshak et al., 2000; Whiteside-Mansell et al., 2003). In each case, the behavior of one family member helps sustain a form of interaction in another that either promotes or undermines children's well-being.

Indirect Influences

The impact of family relationships on child development becomes even more complicated when we consider that interaction between any two family members is affected by others present in the setting. Recall from Chapter 1 that Bronfenbrenner called these indirect influences the effect of *third parties.* Researchers have become intensely interested in how a range of relationships—mother with father, parent with sibling, grandparent with parent—modify the child's direct experiences in the family. In fact, as the Social Issues: Health box on page 570 reveals, a child's birth can have a third-party impact on parents' interaction that may affect the child's development and well-being.

Third parties can serve as supports for development, or they can undermine it. For example, when parents' marital relationship is warm and considerate, mothers and fathers are more likely to engage in effective **coparenting,** mutually supporting each other's parenting behaviors. Such parents have more secure attachment relationships with their babies,

SOCIAL ISSUES: HEALTH

The Transition to Parenthood

The early weeks after a baby enters the family are full of profound changes—constant caregiving, added financial responsibilities, and less time for couples to devote to each other. In response, gender roles of husband and wife usually become more traditional, even for couples strongly committed to gender equality (Cowan & Cowan, 2000; Katz-Wise, Priess, & Hyde, 2010). Mothers change more than fathers as they spend more time at home with the baby; fathers focus more on their provider role.

For most new parents, the arrival of a baby—though often associated with mild declines in relationship satisfaction and communication quality—does not cause significant marital strain. Marriages that are gratifying and supportive tend to remain so (Doss et al., 2009; Feeney et al., 2001; Miller, 2000). But troubled marriages usually become more distressed after a baby is born. In a study of newlyweds who were interviewed annually for six years, the husband's affection, expression of "we-ness" (values and goals similar to his wife's), and awareness of his wife's daily life predicted mothers' stable or increasing marital satisfaction after childbirth. In contrast, the husband's negativity and the couple's out-of-control conflict predicted a drop in mothers' satisfaction (Shapiro, Gottman, & Carrere, 2000).

Violated expectations about division of labor in the home powerfully affect new parents' well-being. In dual-earner marriages, the larger the difference between men's and women's caregiving responsibilities, the greater the decline in marital satisfaction after childbirth, especially for women—with negative consequences for parent–infant interaction. In contrast, sharing caregiving tasks predicts greater parental happiness and sensitivity to the baby (McHale et al., 2004; Moller, Hwang, & Wickberg, 2008). An exception exists, however, for employed lower-SES women who endorse traditional gender roles. When their husbands help extensively with child care, these mothers tend to report more distress, perhaps because they feel disappointed at being unable to fulfill their desire to do most of the caregiving (Goldberg & Perry-Jenkins, 2003).

Postponing parenthood until the late twenties or thirties, as more couples do today, eases the transition to parenthood. Waiting permits couples to pursue occupational goals, gain life experience, and strengthen their relationship. Under these circumstances, men are more enthusiastic about becoming fathers and therefore more willing to participate. And women whose careers are well under way are more likely to encourage their husbands to share housework and child care, which fosters fathers' involvement (Lee & Doherty, 2007; Schoppe-Sullivan et al., 2008).

In a study of well-educated mothers, those who had recently given birth to their second child reported just as much stress as first-time mothers (Krieg, 2007). A second birth typically requires that fathers take an even more active role in parenting—by caring for the firstborn while the mother is recuperating and by sharing in the high demands of tending to both a baby and a young child. Consequently, well-functioning families typically pull back from the traditional division of responsibilities that occurred after the first birth. Fathers' willingness to place greater emphasis on the parenting role is strongly linked to mothers' adjustment after the arrival of a second baby (Stewart, 1990). And the support and encouragement of family, friends, and partner are crucial for fathers' well-being.

Special interventions exist to ease the transition to parenthood. For those who are not at high risk for problems, counselor-led parenting groups are highly effective (Glade, Bean, & Vira, 2005; Petch & Halford, 2008). In one program, first-time expectant couples gathered once a week for six months to discuss their dreams for the family and changes in relationships sparked by the baby's arrival. Eighteen months after the program ended, participating fathers described themselves as more involved with their child than did fathers in a no-intervention condition. Perhaps because of fathers' caregiving assistance, participating mothers maintained their prebirth satisfaction with family and work roles. Three years after the birth, the marriages of all participating couples were still intact and just as happy as they had been before parenthood. In contrast, 15 percent of couples receiving no intervention had divorced (Cowan & Cowan, 1997; Schulz, Cowan, & Cowan, 2006).

High-risk parents struggling with poverty, single parenthood, or the birth of a child with disabilities usually need more intensive intervention. Programs in which a professional intervener visits the home and focuses on enhancing social support and parenting skills have resulted in improved parent–infant interaction and benefits for children's cognitive and social development into middle childhood (Petch & Halford, 2008). For low-income unmarried couples, the father's involvement in the pregnancy (providing the expectant mother with financial and social support, being present at the birth) enhances paternal engagement with the child in the first few years, in part because it increases his commitment to the mother and the chances that the couple will cohabit or marry (Cabrera, Fagan, & Farrie, 2008). Consequently, interventions that encourage unmarried men to be prenatally involved are a promising approach to strengthening family bonds and parenting.

Generous paid employment leave—widely available in industrialized nations but not in the United States—is crucial for easing the transition to parenthood (see page 119 in Chapter 3). Flexible work hours are also helpful. When favorable workplace policies exist and couples try to support each other's needs, the stress caused by the birth of a baby remains manageable.

First-time parents delight in their newborn. In a warm, gratifying marriage, sharing caregiving tasks is related to greater sensitivity toward the baby.

and they praise and stimulate their children more and nag and scold them less. Effective coparenting, in turn, fosters a positive marital relationship (Morrill et al., 2010). In contrast, parents whose marriage is tense and hostile often interfere with one another's child-rearing efforts, are less responsive to children's needs, less consistent in discipline practices, and more likely to criticize, express anger, and punish (Caldera & Lindsey, 2006; Krishnakumar & Buehler, 2000; McHale et al., 2002). Clearly, communication and emotions generated in the marital relationship "spill over" into the parent–child relationship.

Children who are chronically exposed to angry, unresolved parental conflict have myriad problems related to disrupted emotional security and emotional self-regulation (Cummings & Merrilees, 2010; Schacht, Cummings, & Davies, 2009). These include both internalizing difficulties (especially among girls), such as blaming themselves, feeling worried and fearful, and trying to repair their parents' relationship; and externalizing difficulties (especially among boys), including anger and aggression (Cummings, Goeke-Morey, & Papp, 2004; Davies & Lindsay, 2004). Furthermore, in research carried out in nations as diverse as Bangladesh, China, Bosnia, and the United States, parental conflict consistently undermined good parenting by increasing criticism and belittling of adolescents and decreasing monitoring of their whereabouts and activities (Bradford et al., 2003). These parenting practices, in turn, heightened youth behavior problems.

Yet even when parental arguments strain children's adjustment, other family members may help restore effective interaction. Grandparents, for example, can promote children's development both directly, by responding warmly to the child and helping with caregiving (see page 438 in Chapter 10), and indirectly, by providing parents with child-rearing advice, models of child-rearing skill, and sometimes financial assistance. Of course, as with any indirect influence, grandparents can sometimes be harmful. When quarrelsome relations exist between grandparents and parents, parent–child communication and children's adjustment may suffer.

Adapting to Change

Think back to the *chronosystem* in Bronfenbrenner's theory (see page 28 in Chapter 1). The interplay of forces within the family is dynamic and ever-changing, as each member adapts to the development of other members.

For example, as children acquire new skills, parents adjust the way they treat their more competent youngsters. To cite just one example, turn back to Chapter 4, page 147, and review how babies' mastery of crawling leads parents to engage in more game playing and expressions of affection, as well as restriction of the child's activities. These changes in child rearing pave the way for new achievements and further revisions in family relationships. **TAKE A MOMENT...** Can you think of other illustrations of this idea, discussed in earlier chapters?

Parents' development affects children as well. As we will see later, the mild increase in parent–child conflict that often occurs in early adolescence is not solely due to teenagers' striving for independence. This is a time when most parents have reached middle age and—conscious that their children will soon leave home and establish their own lives—are reconsidering their own commitments (Steinberg & Silk, 2002). While the adolescent presses for greater autonomy, the parent presses for more togetherness. This imbalance promotes friction, which parent and teenager gradually resolve by accommodating to changes in each other. Indeed, no social unit other than the family is required to adjust to such vast changes in its members.

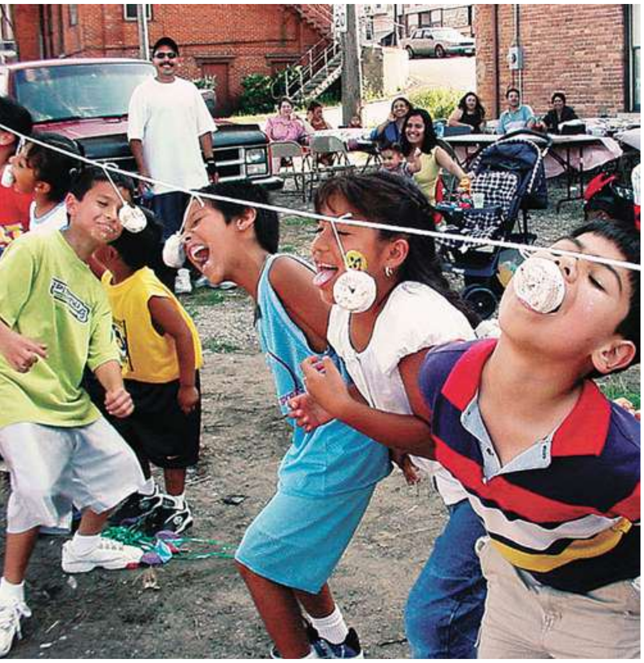
The Family System in Context

The social systems perspective, as we noted earlier, views the family as affected by surrounding social contexts. As the *mesosystem* and *exosystem* in Bronfenbrenner's model make clear, connections to the neighborhood and the larger community—both *formal organizations,* such as school, workplace, recreation center, child-care center, and religious institution, and *informal social networks* of relatives, friends, and neighbors—influence parent–child relationships.

In several studies, low-SES families were randomly assigned vouchers to move out of public housing into neighborhoods varying widely in affluence. Compared with their peers who remained in poverty-stricken areas, children and youths who moved into low-poverty neighborhoods showed substantially better physical and mental health and school achievement (Goering, 2003; Leventhal & Brooks-Gunn, 2003).

Unstable inner-city neighborhoods with dilapidated housing; schools, parks, and playgrounds in disarray; and lack of community centers introduce stressors that undermine parental warmth, involvement, and monitoring and increase parental harshness and inconsistency. In such neighborhoods, family violence, child abuse and neglect, children's problem behavior, youth antisocial activity, and adult criminality are especially high (Brody et al., 2003; Dunn, Schaefer-McDaniel, & Ramsay, 2010). In contrast, strong family ties to the surrounding social context—as indicated by contact with friends and relatives, organized youth activities, and regular church, synagogue, or mosque attendance—reduce family stress and adjustment problems (Boardman, 2004; Leventhal & Brooks-Gunn, 2003).

How do links between family and community reduce stress and promote child development? One answer lies in their provision of *social support,* which leads to the following benefits:



AP IMAGES/MUSCATINE JOURNAL, CONNIE STREET

At an inner-city block party, children participate in a doughnut-eating contest while their parents look on. According to the social systems perspective, community ties are essential for families to function at their best.

- *Parental self-worth.* A neighbor or relative who listens and tries to relieve a parent's concern enhances her self-esteem. The parent, in turn, is likely to interact in a more sensitive and involved manner with her children.
- *Parental access to valuable information and services.* A friend who suggests where a parent might find a job, housing, or affordable child care helps make the multiple roles of spouse, provider, and caregiver easier to fulfill.
- *Child-rearing controls and role models.* Friends, relatives, and other community members may encourage and demonstrate effective parenting practices and discourage ineffective ones.
- *Direct assistance with child rearing.* As children and adolescents participate in their parents' social networks and in youth-oriented community activities, other adults can influence children directly through warmth, stimulation, and exposure to a wider array of competent models. In this way, family–neighborhood ties can reduce the impact of ineffective parenting (Silk et al., 2004). Nearby adults can also intervene when they see young people skipping school or behaving antisocially.

The Better Beginnings, Better Futures Project of Ontario, Canada, is a government-sponsored set of programs aimed at preventing the dire consequences of neighborhood poverty. The most successful of these efforts, using a local elementary school as its base, provided 4- to 8-year-olds with in-class, before- and after-school, and summer enrichment activities. Workers also visited each child's parents regularly, informed them about community resources, and encouraged their involvement in the child's school and neighborhood life. And a community-wide component focused on improving the quality of the neighborhood as a place to live, by offering leadership training and adult education programs and organizing neighborhood safety initiatives and special events and celebrations (Peters, 2005; Peters, Petrunka, & Arnold, 2003). Evaluations as children reached grades 3, 6, and 9 revealed wide-ranging benefits compared with children and families living in other poverty neighborhoods without this set of programs (Peters et al., 2010). Among these were parents' sense of improved marital satisfaction, family functioning, effective child rearing, and community involvement; and gains in children's academic achievement and social adjustment, including positive relationships with peers and adults, prosocial behavior, self-regulation, and a reduction in emotional and behavior problems.

No researcher could possibly study all aspects of the social systems perspective on the family at once. But throughout this chapter, we will continually see examples of how its interlocking parts combine to influence development.

ASK YOURSELF

Review ■ Links between family and community are essential for children's well-being. Provide examples and research findings that support this idea.

Connect ■ How does the goodness-of-fit model, discussed in Chapter 10 (see page 426), illustrate central features of the social systems perspective on family functioning?

Apply ■ At the mall, you see a father getting angry with his young son. Using the social systems perspective, list as many factors as you can that might account for the father's behavior.

Reflect ■ Did any third parties—grandparents, aunts or uncles, or others—influence your relationship with your parents when you were a child? Describe how they affected interactions within your family.

Socialization Within the Family

- Discuss child-rearing styles, and explain how effective parents adapt child rearing to children's growing competence.
- Describe socioeconomic and ethnic variations in child rearing, including the impact of affluence and poverty.

Among the family's functions, socialization centers on children's development. Parents start to socialize their children in earnest during the second year, when toddlers are first able to comply with their directives (see Chapter 12). As children get older, parents gradually step up socialization pressures, but they vary greatly in how they go about the task. In previous chapters, we have seen how parents can foster children's competence—by building a parent–child relationship based on affection and cooperation, by serving as models and reinforcers of mature behavior, by using reasoning and inductive discipline, and by guiding and encouraging children's mastery of new skills. Now let's put these practices together into an overall view of effective parenting.

Styles of Child Rearing

Child-rearing styles are combinations of parenting behaviors that occur over a wide range of situations, creating an enduring child-rearing climate. In a landmark series of studies, Diana Baumrind gathered information on child rearing by watching parents interact with their preschoolers (Baumrind, 1971; Baumrind & Black, 1967). Her findings, and those of others who have extended her work, reveal three features that consistently differentiate an effective style from less effective ones: (1) *acceptance* of the child and *involvement* in the child's life, which establishes an emotional connection with the child; (2) *behavioral control* of the child through expectations, rules, and supervision, which promotes more mature behavior; and (3) *autonomy granting,* which encourages self-reliance (Barber & Olsen, 1997; Gray & Steinberg, 1999; Hart, Newell, & Olsen, 2003; Maccoby & Martin, 1983). Table 14.1 on page 574 shows how child-rearing styles differ in these features. Let's discuss each style in turn.

Authoritative Child Rearing

The **authoritative child-rearing style**—the most successful approach—involves high acceptance and involvement, adaptive control techniques, and appropriate autonomy granting. Authoritative parents are warm, attentive, and sensitive to their child's needs. They establish an enjoyable, emotionally fulfilling parent–child relationship that draws the child into close connection. At the same time, authoritative parents exercise firm, reasonable behavioral control: They insist on appropriate maturity, give reasons for their expectations, use disciplinary encounters as "teaching moments" to promote the child's self-regulation, and monitor their child's whereabouts and activities. Furthermore, authoritative parents engage in gradual, appropriate *autonomy granting,* allowing the child to make decisions in areas where he is ready to make choices. They also place a premium on communication, encouraging the child to express her thoughts, feelings, and desires. And when parent and child disagree, authoritative parents engage in joint decision making when

By granting children autonomy appropriate to their age and abilities, authoritative parents promote competence and maturity. This 9-year-old takes responsibility for helping to create a public garden in the Little Haiti neighborhood of Miami, Florida.

TABLE 14.1 **Features of Child-Rearing Styles**

CHILD-REARING STYLE	ACCEPTANCE AND INVOLVEMENT	CONTROL	AUTONOMY GRANTING
Authoritative	Is warm, responsive, attentive, patient, and sensitive to the child's needs	Engages in adaptive behavioral control: Makes reasonable demands for mature behavior and consistently enforces and explains them	Permits the child to make decisions in accord with readiness Encourages the child to express thoughts, feelings, and desires When parent and child disagree, engages in joint decision making when possible
Authoritarian	Is cold and rejecting	Engages in coercive behavioral control: Makes excessive demands for mature behavior, using force and punishment Often uses psychological control, manipulating and intruding on the child's individuality and parental attachments	Makes decisions for the child Rarely listens to the child's point of view
Permissive	Is warm but overindulgent or inattentive	Is lax in behavioral control: Makes few or no demands for mature behavior	Permits the child to make many decisions before the child is ready
Uninvolved	Is emotionally detached and withdrawn	Is lax in behavioral control: Makes few or no demands for mature behavior	Is indifferent to the child's decision making and point of view

possible. Their willingness to accommodate to the child's perspective increases the likelihood that the child will listen to their perspective in situations where compliance is vital (Kuczynski & Lollis, 2002; Russell, Mize, & Bissaker, 2004).

Throughout childhood and adolescence, authoritative parenting is linked to many aspects of competence—an upbeat mood, self-control, task persistence, academic achievement, cooperativeness, high self-esteem, responsiveness to parents' views, and social and moral maturity (Amato & Fowler, 2002; Aunola, Stattin, & Nurmi, 2000; Gonzalez & Wolters, 2006; Mackey, Arnold, & Pratt, 2001; Milevsky et al., 2007; Steinberg, Darling, & Fletcher, 1995).

© SW PRODUCTIONS/GETTY IMAGES/PHOTODISC

Authoritarian parents often engage in psychological control, belittling their child and using withdrawal of love as a punishment. In response, children become either anxious and withdrawn or defiant and aggressive.

Authoritarian Child Rearing The **authoritarian child-rearing style** is low in acceptance and involvement, high in coercive behavioral control, and low in autonomy granting. Authoritarian parents appear cold and rejecting. To exert control, they yell, command, criticize, and threaten. "Do it because I said so!" is their attitude. They make decisions for their child and expect the child to accept their word unquestioningly. If the child does not, authoritarian parents resort to force and punishment. They also hold excessively high expectations that do not fit the child's developing capacities.

Children of authoritarian parents are more likely to be anxious, unhappy, and low in self-esteem and self-reliance. When frustrated, they tend to react with hostility and, like their parents, resort to force when they do not get their way. Boys, especially, show high rates of anger and defiance. Although girls also engage in acting-out behavior, they are more likely to be dependent, lacking interest in exploration, and overwhelmed by challenging tasks (Hart et al., 2003; Kakihara et al., 2010; Thompson, Hollis, & Richards, 2003). Children and adolescents exposed to the authoritarian style typically achieve poorly in school. However, because of their parents' concern with controlling their behavior, they tend to achieve better and to commit fewer antisocial acts than peers with undemanding parents—that is, those whose parents use one of the two styles we will consider next (Steinberg, Blatt-Eisengart, & Cauffman, 2006).

Notice how the authoritarian style suppresses children's self-expression and independence. In addition to unwarranted behavioral control ("Do what I say!"), authoritarian parents often engage in **psychological control,** in which they attempt to take advantage of children's psychological needs by intruding on and manipulating their verbal expressions, individuality, and attachments to parents. In an attempt to decide virtually everything for the child, these parents frequently interrupt or put down the child's ideas, decisions, and choice of friends. When they are dissatisfied, they withdraw love, making their affection or attention contingent on the child's compliance. Children and adolescents subjected to psychological control exhibit adjustment problems involving both anxious, withdrawn and defiant, aggressive behaviors. Once again, boys are more likely than girls to respond with rebellious and antisocial acts (Barber & Harmon, 2002; Kakihara et al., 2010; Silk et al., 2003). And having had few opportunities for exploration, they are impaired in identity development once they reach early adulthood (Luyckx et al., 2007).

Permissive Child Rearing

The **permissive child-rearing style** is warm and accepting but uninvolved. Permissive parents are either overindulgent or inattentive and, thus, engage in little behavioral control. Instead of gradually granting autonomy, they allow children to make many decisions for themselves at an age when they are not yet capable of doing so. Their children can eat meals and go to bed whenever they wish and can watch as much television as they want. They do not have to learn good manners or do household chores. Although some permissive parents truly believe in this approach, many others simply lack confidence in their ability to influence their child's behavior (Oyserman et al., 2005).

Children of permissive parents tend to be impulsive, disobedient, and rebellious. Compared with children whose parents exert more behavioral control, they are also overly demanding and dependent on adults, and they show reduced task persistence, poorer academic achievement, and more antisocial behavior. The link between permissive parenting and dependent, nonachieving, rebellious behavior is especially strong for boys (Barber & Olsen, 1997; Baumrind, 1971; Steinberg, Blatt-Eisengart, & Cauffman, 2006).

Uninvolved Child Rearing

The **uninvolved child-rearing style** combines low acceptance and involvement with little behavioral control and general indifference to issues of autonomy. Often these parents are emotionally detached and depressed, so overwhelmed by life stress that they have little time or energy for children. They may respond to the child's immediate demands for easily accessible objects while failing to engage in strategies to promote long-term goals, such as establishing and enforcing rules about homework and social behavior, listening to the child's point of view, providing guidance about appropriate choices, and monitoring the child's whereabouts and activities.

At its extreme, uninvolved parenting is a form of child maltreatment called *neglect*. Especially when it begins early, it disrupts virtually all aspects of development (see Chapter 10, page 422). Even with less extreme parental disengagement, children and adolescents display many problems, including school achievement difficulties, depression, anger, and antisocial behavior (Aunola, Stattin, & Nurmi, 2000; Kurdek & Fine, 1994; Schroeder et al., 2010).

What Makes the Authoritative Style Effective?

Table 14.2 on page 576 summarizes outcomes associated with each child-rearing style just considered. As with other correlational findings, the relationship between the authoritative style and children's competence is open to interpretation. Perhaps parents of well-adjusted children are authoritative because their youngsters have especially cooperative dispositions. Children's characteristics do contribute to the ease with which parents can apply the authoritative style. Recall from earlier chapters that temperamentally fearless, impulsive children and emotionally negative, difficult children are more likely to evoke coercive, inconsistent discipline. At the same time, extra warmth and firm control succeed in modifying these children's maladaptive styles (Cipriano & Stifter, 2010; Kochanska, Philibert, & Barry, 2009; Pettit et al., 2007). And with fearful, inhibited children, parents must suppress their tendency to overprotect and take over solving the child's social problems—practices that, as we saw in Chapter 10, worsen the shy child's difficulties. Instead, inhibited children benefit from extra encouragement to be assertive and to express their autonomy (Nelson et al., 2006; Rubin & Burgess, 2002).

TABLE 14.2 Relationship of Child-Rearing Styles to Development and Adjustment Outcomes

CHILD-REARING STYLE	CHILDHOOD	ADOLESCENCE
Authoritative	Upbeat mood; high self-esteem, self-control, task persistence, academic achievement, and cooperativeness	High self-esteem, academic achievement, and social and moral maturity
Authoritarian	Anxious, withdrawn and defiant, aggressive behavior; unhappy mood; hostile when frustrated; academic achievement difficulties	Less well-adjusted than agemates reared with the authoritative style, but somewhat better academic achievement and less antisocial behavior than agemates reared with permissive or uninvolved styles
Permissive	Impulsive, disobedient, and rebellious; overly demanding and dependent on adults; poor task persistence and academic achievement	Poor academic achievement; defiance and antisocial behavior
Uninvolved	Deficits in attachment, cognition, play, and emotional and social skills	Poor academic achievement, depression, anger, and antisocial behavior

Longitudinal evidence indicates that among children of diverse temperaments, authoritative child rearing in the preschool years predicts maturity and adjustment a decade later in adolescence, whereas authoritarian or permissive child rearing predicts adolescent immaturity and adjustment difficulties. And a variant of authoritativeness in which parents exert strong behavioral control—becoming directive but not coercive—yields just as favorable long-term outcomes as a more democratic approach (Baumrind, Larzelere, & Owens, 2010). Parental directiveness may stem from parents' personalities, child-rearing beliefs, or children's needs. Indeed, as the findings on temperament and parenting just mentioned illustrate, some children, because of their dispositions, require "heavier doses" of certain authoritative features.

Over time, the relationship between parenting and children's attributes becomes increasingly bidirectional as each participant modifies the actions of the other and, on the basis of past interactions, forms expectancies for the other's behavior (Kuczynski, 2003). Consider, for example, an investigation of the consequences of parental monitoring that followed adolescents from ages 14 to 18. The more parents knew about their child's whereabouts and activities, the greater the decline in delinquent acts over time. And the greater the decline in delinquency, the more parents increased in knowledge of their teenager's daily life (Laird et al., 2003).

LOOK and LISTEN

Ask several parents to explain their style of child rearing and why they use it, inquiring about acceptance and involvement, control, and autonomy granting. Look for variations in authoritativeness—more or less behavioral control—and parents' reasons for them.

What explains these bidirectional associations, in which parental monitoring promotes responsible youth behavior, which in turn leads to gains in parental knowledge? Parents who exert appropriate oversight are likely to parent effectively in other ways as well, giving adolescents both less opportunity and less reason to engage in delinquency. And parents who take proactive steps to intervene in their teenager's antisocial acts set the stage for a more positive parent–child relationship, in which teenagers are more willing to provide them with information. In contrast, when monitoring is lax and delinquency rises, parent–adolescent interaction may become increasingly negative. As a result, parents may further disengage from parenting, both to avoid these unpleasant exchanges and to reduce contact with a child whom they have come to dislike.

Most children and adolescents seem to view the affection, appropriate control, and respect for self-determination that make up authoritative child rearing as a well-intentioned parental effort to increase their competence. As a result, even hard-to-rear youngsters gradually respond to authoritativeness with cooperation and maturity, which promote parents' pleasure and approval of the child, sense of self-efficacy at child rearing, and likelihood of continuing to be authoritative. In sum, authoritative child rearing seems to create a *positive emotional context* for parental influence in the following ways:

- Warm, involved parents who are secure in the standards they hold for their children provide models of caring concern as well as confident, self-controlled behavior.
- Children are far more likely to comply with and internalize behavioral control that appears fair and reasonable, not arbitrary and excessive (see Chapter 12).
- Parents who combine warmth with rational and reasonable behavioral control are likely to be more effective reinforcing agents, praising children for striving to meet their expectations and making good use of disapproval, which works best when applied by an adult who has been warm and caring (see Chapter 12).

- By making demands and engaging in autonomy granting that fit with children's ability to take responsibility for their own behavior, authoritative parents let children know that they are competent individuals who can do things successfully for themselves. In this way, parents foster favorable self-esteem and cognitive and social maturity (see Chapter 11).
- Supportive features of the authoritative style are a powerful source of resilience, protecting children from the negative effects of family stress and poverty (Beyers et al., 2003).

Still, a few theorists remain convinced that parenting has little impact on child development. They claim that because parents and children share genes, parents provide children with genetically influenced child rearing that does little more than enhance children's built-in propensities. But as the Biology and Environment box on page 578 confirms, a host of findings demonstrate that parenting does contribute vitally to children's competence.

Adapting Child Rearing to Children's Development

Because authoritative parents continually adapt to children's increasing competence, their practices change with children's age. A gradual lessening of control and increase in autonomy granting promote favorable development.

Parenting in Middle Childhood: Coregulation

In middle childhood, the amount of time children spend with parents declines dramatically. Children's growing independence means that parents must deal with new issues. As one mother described it, "I've struggled with how many chores to assign, how much allowance to give, whether their friends are good influences, and what to do about problems at school. And then there's the challenge of keeping track of them when they're out—or even when they're home and I'm not there to see what's going on."

Despite these new concerns, child rearing becomes easier for parents who established an authoritative style during the early years. Reasoning is more effective with school-age children because of their greater capacity for logical thinking and their increased respect for parents' expert knowledge (Collins, Madsen, & Susman-Stillman, 2002). And children of parents who communicate openly and engage in joint decision making when possible are more likely to listen to parents' perspectives in situations where compliance is vital (Russell, Mize, & Bissaker, 2004).

© RADIUS IMAGES/ALAMY

An 11-year-old phones home during an outing with friends. By engaging in coregulation—letting her take charge of daily activities while exercising general oversight—her parents prepare her for greater independence in adolescence.

As children demonstrate that they can manage daily activities and responsibilities, effective parents gradually shift control from adult to child. They do not let go entirely but, rather, engage in **coregulation,** a form of supervision in which parents exercise general oversight while letting children take charge of moment-by-moment decision making. Coregulation grows out of a warm, cooperative relationship between parent and child based on give-and-take. Parents must guide and monitor from a distance and effectively communicate expectations when they are with their children. And children must inform parents of their whereabouts, activities, and problems so parents can intervene when necessary (Maccoby, 1984). Coregulation supports and protects children while preparing them for adolescence, when they will make many important decisions themselves.

Although school-age children often press for greater independence, they also know how much they need their parents' support. In one study, fifth and sixth graders described parents as the most influential people in their lives, often turning to them for affection, advice, enhancement of self-worth, and assistance with everyday problems (Furman & Buhrmester, 1992).

Parenting in Adolescence: Fostering Autonomy

During adolescence, striving for **autonomy**—a sense of oneself as a separate, self-governing individual—becomes a salient task. Autonomy has two vital aspects: (1) an *emotional component*—relying more on oneself and less on parents for support and guidance—and (2) a *behavioral component*—making

BIOLOGY and ENVIRONMENT

Does Parenting Really Matter?

Several highly publicized reviews of research claim that parents are only minor players in children's development—that their impact is overshadowed by the effects of children's genetic makeup and the peer culture (Harris, 1998, 2002). These conclusions are largely based on evidence that siblings reared in the same family show little resemblance in parent-rated temperament (see Chapter 10, page 425, to review), a finding interpreted to mean that parenting is merely a reaction to children's genetic dispositions and does not change children in any appreciable way. No wonder, say proponents of this position, that many studies report only a weak to moderate parenting effect on children's development. A related contention is that children and adolescents resemble their friends more strongly than their siblings. Therefore, peers must be more powerful than parents in influencing children's behavior.

A host of researchers have refuted these assertions, offering evidence that parents—though not the sole influence—exert a profound impact (Berk, 2005; Collins et al., 2000; Hart, 2007; Hart, Newell, & Olsen, 2003; Maccoby, 2000a; Steinberg, 2001). Let's look at their findings:

- *Well-designed research reveals that the relation between parenting and children's development is sometimes substantial.* For example, in one large-scale study, the correlation between authoritative parenting and adolescents' social responsibility was .76 for mothers, .49 for fathers (Hetherington et al., 1999). Similarly, when parents engage in joint problem solving with their adolescent youngsters; establish firm, consistent control; and monitor the adolescent's whereabouts, research shows strong negative relationships with antisocial behavior (Patterson & Forgatch, 1995).
- *Parenting often has different effects on different children.* When weak associations between parenting and children's development are found, they do not necessarily reflect the feeble impact of parenting. Rather, some child-rearing practices affect different children in different ways. And although parents respond differently to children with different temperaments, the relationship is not just a reactive one. **TAKE A MOMENT...** Cite ways, considered in this and in previous chapters, that parents can modify the maladaptive styles of impulsive, difficult, and shy children.
- *Longitudinal research suggests that parenting affects children's development.* Many longitudinal studies indicate that the influence of parenting on diverse aspects of children's development holds even after controlling for children's earlier characteristics (see, for example, Baumrind, Larzelere, & Owens, 2010; Carlson, 1998; D'Onofrio et al., 2006; Laird et al., 2003). These findings suggest that parents' influence is profound and lasting.
- *Parenting interventions show that when child rearing improves, children's development changes accordingly.* The most powerful evidence that parents matter comes from intervention experiments. In one study, recently divorced single mothers of school-age sons were randomly assigned to 14 weekly sessions of parent training and support. Compared to no-intervention controls, the mothers reduced their use of coercive discipline in the year following intervention, and their sons showed fewer behavior problems and deviant peer associations. In a nine-year follow-up, these changes translated into a reduction in adolescent delinquency (DeGarmo & Forgatch, 2005; Forgatch & DeGarmo, 1999; Forgatch et al., 2009). Furthermore, recall from Chapter 12 that training programs targeting parenting skills can break cycles of parent–child hostility, thereby lessening children's aggressive behavior (see page 523).

© JEFF GREENBERG/PHOTOEDIT

Research confirms that parents profoundly influence children's development. When warm parents provide rich, varied experiences, they foster children's positive capacities.

- *Parents influence children's peer relations.* Children and adolescents resemble their friends because young people choose friends who are similar to themselves. But beginning in the preschool years, parents propel children toward certain peers by managing their social activities. And as we will see in Chapter 15, authoritative child rearing affects the values and inclinations children and adolescents bring to the peer situation and, therefore, their choice of friends and their peer interactions and activities (Furman et al., 2002; Laird et al., 2003; Zhou et al., 2002).
- *Some parenting influences cannot be measured easily.* Many people report memorable moments with parents that made a lasting impression. In contrast, a parent's broken promise or discovered deception can destroy parent–child trust and change the impact of future parenting.

In sum, parenting effects combine in complex ways with many other factors, including heredity and peers. Although the contribution of each factor cannot always be partitioned neatly from the others, parents emerge as vigorously influential in wide-ranging research.

decisions independently by carefully weighing one's own judgment and the suggestions of others to arrive at a well-reasoned course of action (Collins & Laursen, 2004; Steinberg & Silk, 2002). Autonomy is closely related to adolescents' quest for identity. Young people who successfully construct personally meaningful values and life goals are autonomous. They have given up childish dependency on parents for a more mature, responsible relationship.

A variety of changes within the adolescent support autonomy. In Chapter 5, we saw that puberty triggers psychological distancing from parents. In addition, as young people look more mature, parents give them more freedom to think and decide for themselves, more opportunities to regulate their own activities, and more responsibility (McElhaney et al., 2009). Cognitive development also paves the way for autonomy: Gradually, adolescents solve problems and make decisions more effectively. And an improved ability to reason about social relationships leads adolescents to *deidealize* their parents, viewing them as "just people." Consequently, they no longer bend as easily to parental authority as they did when younger.

TAKE A MOMENT... Think back to what we said in earlier chapters about the type of parenting that fosters achievement motivation, identity formation, and moral maturity. You will find a common theme: Effective parenting of adolescents strikes a balance between *connection* and *separation*. In diverse ethnic groups, SES levels, nationalities, and family structures (including single-parent, two-parent, and stepparent), warm, supportive parent–adolescent ties that make appropriate demands for maturity while permitting young people to explore ideas and social roles foster autonomy—predicting high self-reliance, effortful control, academic achievement, work orientation, favorable self-esteem, social competence, and ease of separating in the transition to college (Bean, Barber, & Crane, 2007; Eisenberg et al., 2005b; Supple et al., 2009; Vazsonyi, Hibbert, & Snider, 2003; Wang, Pomerantz, & Chen, 2007).

Conversely, parents who are coercive or psychologically controlling interfere with the development of autonomy. These tactics are linked to low self-esteem, depression, drug and alcohol use, and antisocial behavior—outcomes that often persist into adulthood (Barber, Stolz, & Olsen, 2005; Bronte-Tinkew, Moore, & Carrano, 2006; Wissink, Deković, & Meijer, 2006).

Nevertheless, parents often report that living with teenagers is stressful. Earlier we described the family as a *system* that must adapt to changes in its members. The rapid physical and psychological changes of adolescence trigger conflicting expectations in parent–child relationships. In Chapter 12, we noted that interest in making choices about personal matters strengthens in adolescence. Yet parents and teenagers—especially young teenagers—differ sharply on the appropriate age for granting certain privileges, such as control over clothing, school courses, going out with friends, and dating (Smetana, 2002). Parents typically say that the young person is not yet ready for these signs of independence at a point when the teenager thinks they should have been granted long ago! Consistent parental monitoring of the young person's daily activities, through a cooperative relationship in which the adolescent willingly discloses information, is linked to a variety of positive outcomes—prevention of delinquency, reduction in sexual activity, improved school performance, and positive psychological well-being (Crouter & Head, 2002; Jacobson & Crockett, 2000).

© ELLEN B. SENISI/THE IMAGE WORKS

At times, adolescents assert their autonomy by resisting parental authority. But most maintain close parental ties, especially when parents give them the freedom to explore ideas and social roles.

Parents' own development can also lead to conflict with teenagers. While their children face a boundless future and a wide array of choices, middle-aged parents must come to terms with the fact that their own possibilities are narrowing (Holmbeck, 1996). Often parents can't understand why the adolescent wants to skip family activities to be with peers. And teenagers fail to appreciate that parents want the family to be together as often as possible because an important period in their adult life—child rearing—will soon end.

Immigrant parents from cultures that place a high value on family closeness and obedience to authority have greater difficulty adapting to their teenagers' push for autonomy, often reacting more strongly to adolescent disagreement (Phinney & Ong, 2001). And as adolescents acquire the host culture's language and are increasingly exposed to its individualistic values, immigrant parents may become even more critical, prompting teenagers to rely less on the family network for social support. The resulting *acculturative stress* (see page 475 in Chapter 11) is associated with a decline in self-esteem and a rise in anxiety, depressive symptoms, and deviant behavior, including alcohol use and delinquency (Crane et al., 2005; Park, 2009; Suarez-Morales & Lopez, 2009; Warner et al., 2006).

Throughout adolescence, the quality of the parent–child relationship is the single most consistent predictor of mental health. In well-functioning families, young people remain attached to parents and seek their advice, but they do so in a context of greater freedom (Collins & Steinberg, 2006; Steinberg, 2001). The mild conflict that typically arises facilitates adolescent identity and autonomy by helping family members learn to express and tolerate disagreement. Conflicts also inform parents of adolescents' changing needs and expectations, signaling a need for adjustments in the parent–child relationship.

By middle to late adolescence, most parents and children achieve this mature, mutual relationship, and harmonious interaction is on the rise. The reduced time that Western teenagers spend with their families—for U.S. youths, a drop from 33 percent of waking hours in fifth grade to 14 percent in twelfth grade—has little to do with conflict (Larson et al., 1996). Rather, it results from the large amount of unstructured time available to teenagers in North America and Western Europe—on average, nearly half their waking hours (Larson, 2001). Young people tend to fill these free hours with activities that take them away from home—part-time jobs, a growing array of leisure and volunteer pursuits, and time with friends.

But this drop in family time is not universal. In one study, urban low- and middle-SES African-American youths showed no decline from childhood to adolescence in hours spent at home with family—a typical pattern in cultures with collectivist values (Larson et al., 2001). Furthermore, teenagers living in risky neighborhoods tend to have more trusting relationships with parents and adjust more favorably when their parents maintain tighter control and pressure them not to engage in worrisome behaviors (McElhaney & Allen, 2001). In harsh surroundings, young people seem to interpret more measured granting of autonomy as a sign of parental caring.

Socioeconomic and Ethnic Variations in Child Rearing

Study after study confirms that the authoritative style predicts favorable development in children and adolescents varying widely in SES and culture (Crouter & Head, 2002; Slicker & Thornberry, 2002; Vazonyi, Hibbert, & Snider, 2003). At the same time, SES and ethnic differences in parenting do exist.

Socioeconomic Status

As SES rises and falls, parents and children face changing circumstances that affect family functioning, with each component of SES (educational attainment, occupational prestige and skill, and income) contributing. Researchers have yet to unravel these specific influences. Education and earnings are powerfully influential, with occupation playing a lesser but nevertheless important role (Duncan & Magnusson, 2003).

SES is linked to timing of parenthood and to family size. People who work in skilled and semiskilled manual occupations (for example, construction workers, truck drivers, and custodians) tend to marry and have children earlier, as well as give birth to more children, than people in professional and technical occupations. The two groups also differ in child-rearing values and expectations. When asked about personal qualities they desire for their children, lower-SES parents tend to emphasize external characteristics, such as obedience, politeness, neatness, and cleanliness. In contrast, higher-SES parents emphasize psychological traits, such as curiosity, happiness, self-direction, and cognitive and social maturity (Duncan & Magnusson, 2003; Hoff, Laursen, & Tardif, 2002; Lareau, 2003).

These differences are reflected in family interaction. Parents higher in SES talk to, read to, and otherwise stimulate their babies and preschoolers more (see Chapter 9, page 378). With older children and adolescents, they use more warmth, explanations, inductive discipline, and verbal praise; set higher academic and other developmental goals; and allow their children to make more decisions. Commands ("Do that because I told you to"), criticism, and physical punishment all occur more often in low-SES households (Bush & Peterson, 2008; Mandara et al., 2009).

Education contributes substantially to these differences. Higher-SES parents' interest in providing verbal stimulation and nurturing inner traits is supported by years of schooling, during which they learned to think about abstract, subjective ideas and, thus, to invest in their children's cognitive and social development (Mistry et al., 2008; Vernon-Feagans et al., 2008). At the same time, greater economic security enables parents to devote more time, energy, and material resources to nurturing their children's psychological characteristics

(Cheadle & Amato, 2011; Votruba-Drzal, 2003). In contrast, high levels of stress sparked by economic insecurity contribute to low-SES parents' reduced provision of stimulating interaction and activities as well as greater use of coercive discipline (Brooks-Gunn, Klebanov, & Duncan, 1996; Chin & Phillips, 2004; Conger & Donnellan, 2007).

Because of limited education and low social status, many low-SES parents feel powerless in their relationships beyond the home. At work, for example, they must obey the rules of others in positions of authority. When they get home, their parent–child interaction seems to duplicate these experiences—but now they are in authority. Higher-SES parents, in contrast, typically have more control over their own lives. At work, they are used to making independent decisions and convincing others of their point of view. At home, they are more likely to teach these skills to their children (Greenberger, O'Neil, & Nagel, 1994).

Poverty When families slip into poverty, effective parenting and children's development are profoundly threatened. Consider Zinnia Mae, who grew up in a close-knit black community located in a small southeastern American city (Heath, 1990). As unemployment struck the community and citizens moved away, 16-year-old Zinnia Mae caught a ride to Atlanta. Two years later, she was the mother of a daughter and twin boys, and she had moved into high-rise public housing.

Zinnia Mae worried constantly about scraping together enough money to put food on the table, finding baby-sitters so she could go to the laundry or grocery, freeing herself from rising debt, and locating the twins' father, who had stopped sending money. Her most frequent words were, "I'm so tired." The children had only one set meal—breakfast; otherwise, they ate whenever they were hungry or bored. Their play space was limited to the living-room sofa and a mattress on the floor. Toys consisted of scraps of a blanket, spoons and food cartons, a small rubber ball, a few plastic cars, and a roller skate abandoned in the building. At a researcher's request, Zinnia Mae agreed to tape-record her interactions with her children. Cut off from family and community ties and overwhelmed by financial strain and feelings of helplessness, she found herself unable to join in activities with her children. In 500 hours of tape, she started a conversation with them only 18 times.

AP IMAGES/THE DECATUR DAILY/JONATHAN PALMER

This family, already struggling financially, became homeless after a trailer park fire. The persistent stressors that accompany poverty weaken the family system, with profoundly negative consequences for children's well-being.

The constant stressors that accompany poverty gradually weaken the family system. Poor families have many daily hassles—bills to pay, the car breaking down, loss of welfare and unemployment payments, something stolen from the house, to name just a few. When daily crises arise, parents become depressed, irritable, and distracted; hostile interactions increase; and children's development suffers (Conger & Donnellan, 2007; Evans, 2006). Negative outcomes are especially severe in single-parent families, in families who must live in poor housing and dangerous neighborhoods, and in homeless families—conditions that make everyday existence even more difficult, while reducing social supports that assist in coping with economic hardship (Hart, Atkins, & Matsuba, 2008; Leventhal & Brooks-Gunn, 2003).

Besides stress and conflict, reduced parental involvement and depleted home learning environments (like that of Zinnia Mae) profoundly affect poor children's cognitive and emotional well-being. As noted in earlier chapters, poverty that begins early and persists has devastating effects on children's physical and mental health, intelligence, and school achievement.

Affluence Despite their advanced education and greater material wealth, affluent parents—those in prestigious occupations with six-figure annual incomes—too often fail to engage in family interaction and parenting that promote favorable development. In several studies, researchers tracked youths growing up in high-SES suburbs (Luthar & Latendresse, 2005a). By seventh grade, many showed serious problems that worsened in high school. Their school grades were poor, and they were more likely than low-SES youths to engage in alcohol and drug use and to report high levels of anxiety and depression (Luthar & Becker, 2002; Luthar & Goldstein, 2008). Furthermore, among affluent (but not low-SES) teenagers, substance use was correlated with anxiety and depression, suggesting that wealthy youths took drugs to self-medicate—a practice that predicts persistent abuse (Luthar & Sexton, 2004).

Why are so many affluent youths troubled? Compared to their better-adjusted counterparts, poorly adjusted affluent young people report less emotional closeness and supervision from their parents, who lead professionally and socially demanding lives. As a group, wealthy parents are nearly as physically and emotionally unavailable to their youngsters as parents coping with serious financial strain. At the same time, these parents often make excessive demands for achievement (Luthar & Becker, 2002). Adolescents whose parents value their accomplishments more than their character and emotional well-being are more likely to have academic and emotional problems.

For both affluent and low-SES youths, a simple routine—eating dinner with parents—is associated with a reduction in adjustment difficulties, even after many other aspects of parenting are controlled (see Figure 14.1) (Luthar & Latendresse, 2005b). Interventions that make wealthy parents aware of the high costs of a competitive lifestyle and minimal family time are badly needed.

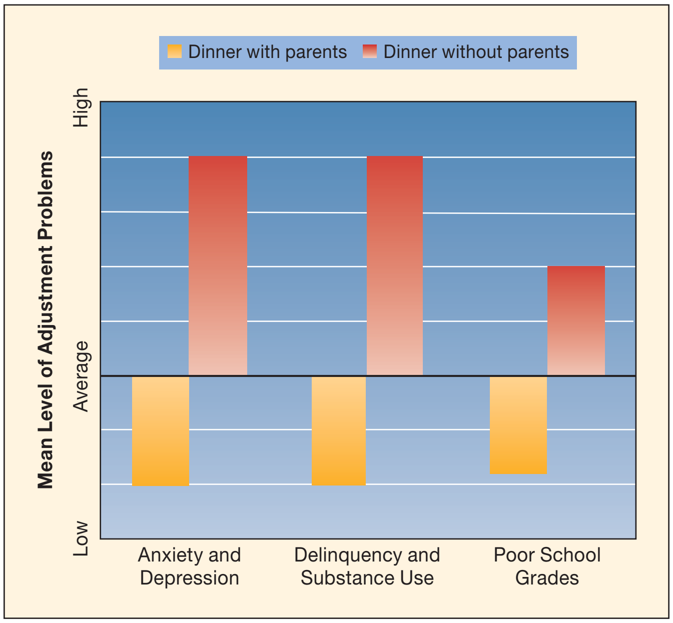

FIGURE 14.1 Relationship of regularly eating dinner with parents to affluent youths' adjustment problems. Compared with sixth graders who often ate dinner with their parents, those who rarely did so were far more likely to display anxiety and depression, delinquency and substance use, and poor school grades, even after many other aspects of parenting were controlled. In this study, frequent family mealtimes also protected inner-city youths from delinquency and substance use and from classroom learning problems. (Adapted from Luthar & Latendresse, 2005b.)

Ethnicity Although authoritative parenting is broadly advantageous, ethnic minority parents often have distinct child-rearing beliefs and practices that reflect cultural values and family context. Let's take some examples.

Compared with Western parents, Chinese parents describe their parenting as less warm and more controlling. They are more directive in teaching and scheduling their children's time, as a way of fostering self-control and high achievement. Chinese parents may appear less warm than Western parents because they withhold praise, which they believe results in self-satisfied and poorly motivated children (Chao, 1994; Chen, 2001). High control reflects the Confucian belief in strict discipline, respect for elders, and socially desirable behavior, taught by deeply involved parents. Chinese parents report expressing affection and concern and using induction and other reasoning-oriented discipline as much as American parents do, but they more often shame a misbehaving child (see Chapter 10), withdraw love, and use physical punishment (Cheah et al., 2009; Shwalb et al., 2004; Wu et al., 2002). When these practices become excessive, resulting in an authoritarian style high in psychological or coercive control, Chinese children display the same negative outcomes as Western children: poor academic achievement, anxiety, depression, and aggressive behavior (Chan, 2010; Nelson et al., 2005, 2006; Pong, Johnston, & Chen, 2010; Wang, Pomerantz, & Chen, 2007).

In Hispanic families, Asian Pacific Island families, and Caribbean families of African and East Indian origin, firm insistence on respect for parental authority is paired with high parental warmth—a combination suited to promoting competence and strong feelings of family loyalty (Harrison et al., 1994; Roopnarine & Evans, 2007). In one study, Mexican-American mothers living in poverty who adhered strongly to their cultural traditions tended to combine warmth with strict, even somewhat harsh, control—a style that served a protective function, in that it was associated with reduced child and adolescent conduct problems (Hill, Bush, & Roosa, 2003). Although at one time viewed as coercive, contemporary Hispanic-American fathers typically spend much time with their children and are warm and sensitive (Cabrera & García Coll, 2004; Jambunathan, Burts, & Pierce, 2000). In Caribbean families that have immigrated to the United States, fathers' authoritativeness—but not mothers'—predicted preschoolers' literacy and math skills, probably because Caribbean fathers take a larger role in guiding their children's academic progress (Roopnarine et al., 2006).

In Hispanic families, respect for parental authority is often paired with high parental warmth—a combination that promotes competence and strong family loyalty.

CULTURAL INFLUENCES

The African-American Extended Family

The African-American extended family can be traced to the African heritage of most black Americans. In many African societies, newly married couples do not start their own households. Instead, they live with a large extended family, which assists its members with all aspects of daily life. This tradition of maintaining a broad network of kinship ties traveled to North America during the period of slavery. Since then, it has served as a protective shield against the destructive impact of poverty and racial prejudice on African-American family life. Today, more black than white adults have relatives other than their own children living in the same household. African-American parents also live closer to kin, often establish family-like relationships with friends and neighbors, see more relatives during the week, and perceive relatives as more important in their lives (Boyd-Franklin, 2006; McAdoo & Younge, 2009).

By providing emotional support and sharing income and essential resources, the African-American extended family helps reduce the stress of poverty, single parenthood, and inner-city neighborhood disorganization (Jarrett, Jefferson, & Kelly, 2010). Extended-family members often help with child rearing, and adolescent mothers living in extended families are more likely to complete high school, get a job, and avoid dependence on welfare than mothers living on their own—factors that in turn benefit children's well-being (Gordon, Chase-Lansdale, & Brooks-Gunn, 2004; Trent & Harlan, 1994).

For single mothers who were very young at the time of their child's birth, extended-family living continues to be associated with more positive mother–child interaction during the preschool years. Otherwise, establishing an independent household with the help of nearby relatives is related to improved child rearing. Perhaps this arrangement permits the more mature teenage mother who has developed effective parenting skills to implement them (Chase-Lansdale, Brooks-Gunn, & Zamsky, 1994). In families rearing adolescents, kinship support increases the likelihood of effective parenting, which is related to adolescents' self-reliance, emotional well-being, and reduced antisocial behavior (Simons et al., 2006; Taylor, 2010).

Finally, the extended family plays an important role in transmitting African-American culture. Compared with nuclear family households, extended-family arrangements place more emphasis on cooperation and moral and religious values. And older black adults, such as grandparents and great-grandparents, regard educating children about their African heritage as especially important (Mosley-Howard & Evans, 2000; Taylor, 2000). Family reunions—sometimes held in grandparents' and great-grandparents' hometowns in the South—are especially common among African Americans, giving young people a strong sense of their roots (Boyd-Franklin, 2006). These influences strengthen family bonds, protect children's development, and increase the chances that the extended-family lifestyle will carry over to the next generation.

© JEFF GREENBERG/THE IMAGE WORKS

Three generations come together at a neighborhood festival. Strong bonds with extended family members have helped protect many African-American children against the destructive impact of poverty and racial prejudice.

Although wide variation exists, low-SES African-American parents tend to expect immediate obedience. But like findings just reported for Mexican Americans, when African-American families live in depleted, crime-ridden neighborhoods and have few social supports, strict control may have a positive effect, preventing antisocial involvements. Other research suggests that black parents use firm control for broader reasons—to promote self-reliance, self-regulation, and a watchful attitude in risky surroundings, which protects children from becoming victims of crime. Consistent with this view, low-SES African-American parents who use more controlling strategies tend to have more cognitively and socially competent children (Brody & Flor, 1998). Recall, also, that a history of physical punishment is associated with a reduction in antisocial behavior among African-American adolescents but with an increase among Caucasian-American adolescents (see page 493 in Chapter 12). Most African-American parents who use strict, "no-nonsense" discipline use physical punishment sparingly and combine it with warmth and reasoning.

The family structure and child-rearing customs of many minorities buffer the stress and disorganization caused by poverty. As the Cultural Influences box above illustrates, the **extended-family household,** in which one or more adult relatives live with the parent–child nuclear family unit, is a vital feature of ethnic minority family life that has enabled many families to rear children successfully, despite severe economic deprivation and prejudice. Extended family ties provide yet another example of the remarkable capacity of families to mobilize their cultural traditions to safeguard children's development under conditions of high life stress.

ASK YOURSELF

Review ■ Explain why authoritative parenting is linked to favorable academic and social outcomes among children and adolescents. Is the concept of authoritative parenting useful for understanding effective parenting across cultures? Explain.

Connect ■ How do factors that promote autonomy in adolescence also foster identity development? (To review the influence of parenting on identity, see page 473 in Chapter 11.)

Apply ■ Prepare a short talk for a parent–teacher organization, maintaining that parents matter greatly in children's lives. Support each of your points with research evidence.

Reflect ■ How would you classify your parents' child-rearing styles? What factors might have influenced their approach to child rearing?

- Describe the influence of family size on child rearing, and explain how sibling relationships affect development.
- How do children fare in adoptive, gay and lesbian, and never-married single-parent families?
- What factors influence children's adjustment to divorce and blended-family arrangements?
- How do maternal employment and life in dual-earner families affect children's development?
- Discuss the influence of child-care quality on preschoolers' development and the impact of self-care on school-age children's adjustment.

Family Lifestyles and Transitions

Families in industrialized nations have become more diverse. Today, there are fewer births per family unit, more adults who want to adopt, more lesbian and gay parents who are open about their sexual orientation, and more never-married parents. Further, high rates of divorce, remarriage, and maternal employment have reshaped the family system.

In the following sections, we discuss these changes in the family, emphasizing how each affects family relationships and children's development. **TAKE A MOMENT...** As you consider this array of family forms, think back to the social systems perspective. Note how children's well-being, in each instance, depends on the quality of family interaction, which is sustained by supportive ties to kin and community and by favorable public policies.

From Large to Small Families

In 1960, the average number of children per American woman of childbearing age was 3.1. Currently, it is 2.1 in the United States, 1.9 in the United Kingdom, 1.8 in Australia, 1.7 in Sweden, 1.6 in Canada, 1.4 in Germany, and 1.3 in Italy and Japan (U.S. Census Bureau, 2011a, 2011b).

In addition to more effective birth control, a major reason for this decline is that a family size of one or two children is more compatible with a woman's decision to divide her energies between family and work. The tendency of many couples to delay having children until they are well-established professionally and secure economically (see Chapter 3) also contributes to smaller family size. Furthermore, marital instability plays a role: More couples today get divorced before their childbearing plans are complete. Finally, caring for children and providing them with opportunities is expensive—yet another contributing factor to a smaller family size. According to a conservative estimate, today's new parents in the United States will spend about $280,000 to rear a child from birth to age 18, and many will incur substantial additional expense for higher education (U.S. Department of Agriculture, 2011a).

Family Size and Child Development Popular advice to prospective parents often recommends limiting family size in the interests of "child-rearing quality"—more parental affection, attention, and material resources per child, which enhance children's intellectual development. Do large families really make less intelligent children, as prevailing attitudes suggest? To find out, researchers turned to a large, two-generation longitudinal study.

Starting in 1972, the U.S. National Longitudinal Survey of Youth (NLSY) followed a representative sample of several thousand U.S. 14- to 22-year-olds; in 1986 the children of the original participants were added to the investigation. Because both cohorts took intelligence tests, the researchers could examine the relationship of sibling birth order within families to IQ, to find out whether having additional children depresses children's intellectual functioning.

As the horizontal lines in Figure 14.2 reveal, children's mental test performance did not decline with later birth order—a finding that contradicts the belief that having more children depresses their intellectual ability. At the same time, the differences among the lines show that the larger the family, the lower the scores of all siblings. The researchers also found that the link between family size and children's IQ can be explained by a strong trend for mothers who score lower in intelligence to give birth to more children (Rodgers et al., 2000). In other NLSY research, among children of bright, economically advantaged mothers, the family size–IQ correlation disappeared (Guo & VanWey, 1999). This suggests that low SES contributes powerfully to the lower IQs of both mothers and children in large families.

Other evidence confirms that rather than parenting quality declining as new children are born, parents reallocate their energies. In a longitudinal study of a nationally representative sample of Canadian two-parent families, new births led to a decrease in maternal affection toward older siblings, though most mothers probably remained generally warm. At the same time, the consistency of parenting—the extent to which mothers insisted that older children meet their expectations for mature behavior, such as completing chores, doing homework, and treating other respectfully—rose over time (Strohschein et al., 2008). After a new baby joined the family, mothers seemed to reorganize their parenting practices to best meet all their children's needs.

In sum, although many good reasons exist for limiting family size, the concern that additional births will reduce child-rearing effectiveness and, thus, children's intelligence and life chances is not warranted. Rather, young people with lower mental test scores—many of whom dropped out of school, live in poverty, lack hope for their future, and fail to engage in family planning—are most likely to have large families (Amato et al., 2008). For adolescents with these risk factors, educational and family planning interventions are crucial (see Chapter 5, page 220).

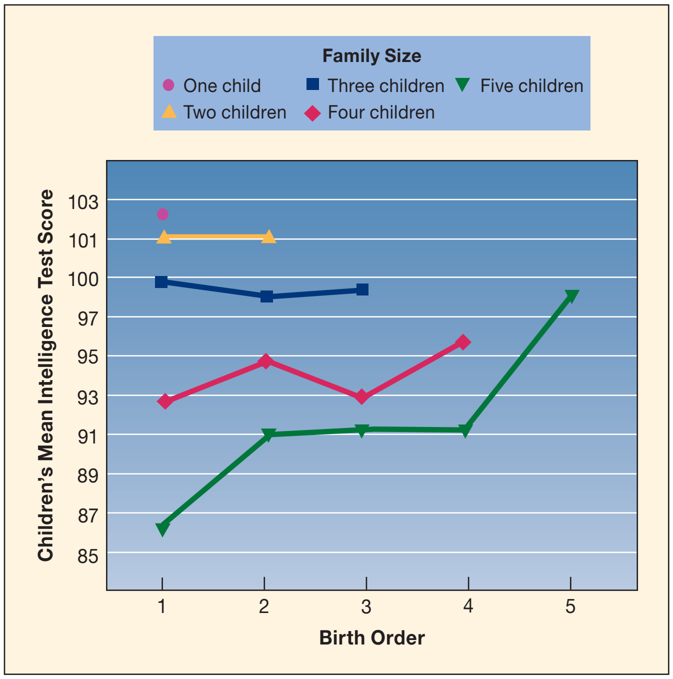

FIGURE 14.2 **Relationship of birth order and family size to intelligence.** In the U.S. National Longitudinal Survey of Youth, children's IQs did not decline with later birth order, as would be predicted if large families diluted the quality of children's experiences. To the contrary, in the largest families, the youngest children tended to score higher than their siblings. But note the differences among the lines, which indicate that the larger the family, the lower the scores of all siblings. (From J. L. Rodgers, H. H. Cleveland, E. van den Oord, & D. C. Rowe, 2000, "Resolving the Debate over Birth Order, Family Size, and Intelligence," *American Psychologist, 55,* p. 607. Copyright © 2000 by the American Psychological Association. Reprinted by permission of the American Psychological Association.)

Growing Up with Siblings Despite declines in family size, 80 percent of North American and European children grow up with at least one sibling (Dunn, 2004b). Siblings influence development both directly, through relationships with one another, and indirectly, through the impact of an additional child on parents' behavior. In previous chapters, we examined some consequences of having brothers and sisters, including effects on early language development, personality, self- and social understanding, and gender typing. Now let's look closely at the quality of the sibling relationship.

Emergence of Sibling Relationships. The arrival of a baby brother or sister is a difficult experience for most preschoolers, who—realizing that they must now share their parents' attention and affection—often become demanding, clingy, and deliberately naughty for a time. Attachment security also typically declines, especially for children over age 2 (old enough to feel threatened and displaced) and for those with mothers under stress (Baydar, Greek, & Brooks-Gunn, 1997; Teti et al., 1996).

Yet resentment is only one feature of a rich emotional relationship that soon develops between siblings. Older children also show affection and sympathetic concern—kissing and patting the baby and calling out, "Mom, he needs you," when the infant cries. By the end of the first year, babies usually spend much time with older siblings and are comforted by their presence during short parental absences. Throughout childhood, children continue to treat older siblings as attachment figures, turning to them for comfort in stressful situations when parents are unavailable (Seibert & Kerns, 2009).

Because of their frequency and emotional intensity, sibling interactions are unique contexts in which social competence expands. In the second year, toddlers often imitate and join in play with their brothers and sisters, and between their second and fourth birthdays, they gradually take more active roles. Siblings who are close in age relate to one another on a more equal footing than parents and children. They often engage in joint pretend, talk about feelings, tease, deceive, and—when conflicts arise—call attention to their own wants and needs. The skills acquired through these experiences contribute to understanding of emotions and other mental states, perspective taking, moral maturity, and competence in relating to peers (Kramer, 2011). Consistent with these outcomes, positive sibling ties predict favorable adjustment, even among hostile children at risk for social difficulties (Modry-Mandell, Gamble, & Taylor, 2007; Stormshak et al., 1996).

Nevertheless, individual differences in sibling relationships emerge soon after the new baby's arrival. Certain temperamental traits—high emotional reactivity or activity level—increase the chances of sibling conflict (Brody, Stoneman, & McCoy, 1994; Dunn, 1994). Parenting is also influential: Maternal warmth toward both children is related to positive sibling interaction and to preschoolers' support of a distressed younger sibling (Volling, 2001; Volling & Belsky, 1992). And mothers who frequently play with their children and head off potential conflicts by explaining the toddler's wants and needs to the preschool sibling foster sibling cooperation. In contrast, maternal harshness and lack of involvement result in increasingly antagonistic sibling relationships (Howe, Aquan-Assee, & Bukowski, 2001).

Finally, a good marriage is linked to preschool siblings' capacity to cope adaptively with jealousy and conflict (Volling, McElwain, & Miller, 2002). Perhaps good communication between parents serves as a model of effective problem solving. It may also foster a generally happy family environment, giving children less reason to feel jealous.

LOOK and LISTEN

Arrange to observe a toddler and preschooler sibling pair at home for about an hour, recording instances of sibling cooperation and conflict along with parental interventions. How would you sum up the quality of this sibling relationship?

Sibling Relationships in Middle Childhood. Sibling rivalry tends to increase in middle childhood. As children participate in a wider range of activities, parents often compare siblings' traits and accomplishments. The child who gets less parental affection, more disapproval, or fewer material resources is likely to be resentful and show poorer adjustment over time (Dunn, 2004b; Tamrouti-Makkink et al., 2004).

For same-sex siblings who are close in age, parental comparisons are more frequent, resulting in more quarreling and antagonism. This effect is particularly strong when parents are under stress as a result of financial worries, marital conflict, single parenthood, or child negativity (Jenkins, Rasbash, & O'Connor, 2003). Parents whose energies are drained become less careful about being fair. Perhaps because fathers, overall, spend less time with children than mothers do, children react especially intensely when fathers prefer one child (Brody, Stoneman, & McCoy, 1992).

Although sibling rivalry tends to increase in middle childhood, siblings also provide each other with emotional support and, sometimes, patient help with difficult tasks.

© BRUCE LAURANCE/GETTY IMAGES/BLEND IMAGES

Although conflict rises, most school-age siblings continue to rely on one another for companionship, assistance, and emotional support (Siebert & Kerns, 2009). When researchers asked siblings about shared daily activities, children mentioned that older siblings often helped younger siblings with academic and peer challenges. And both offered each other help with family issues (Tucker, McHale, & Crouter, 2001). But for siblings to reap these benefits, parental encouragement of warm, considerate sibling ties is vital. The more positive their relationship, the more siblings resolve disagreements constructively, turn to one another for emotional support and concrete forms of assistance, and contribute to resilience in the face of major stressors, such as parental separation and divorce (Conger, Stocker, & McGuire, 2009; Soli, McHale, & Feinberg, 2009).

When siblings get along well, the older sibling's academic and social competence tends to "rub off on" the younger sibling, fostering higher achievement and more positive peer relations (Brody & Murry, 2001; Lamarche et al., 2006). But destructive sibling conflict in middle childhood is associated with detrimental outcomes, including conflict-ridden peer relationships, anxiety, depressed mood, and later substance use and delinquency, even after other family relationship factors are controlled (Criss & Shaw, 2005; Kim et al., 2007; Stocker, Burwell, & Briggs, 2002).

Providing parents with training in mediation—how to get siblings to lay down ground rules, clarify points of agreement and disagreement, and discuss possible solutions—increases siblings' awareness of one another's perspectives and reduces animosity (Smith & Ross, 2007). And direct intervention with sibling pairs, in sessions that teach emotional understanding, perspective taking, emotional self-regulation, and conflict management, enhances positive interaction and reduces the need for parents to intervene in siblings' negative emotional exchanges (Kennedy & Kramer, 2008).

Sibling Relationships in Adolescence. Like parent–child relationships, sibling interactions adapt to development at adolescence. As younger siblings become more self-sufficient, they accept less direction from their older brothers and sisters, and sibling influence declines. Also, as teenagers become more involved in friendships and romantic relationships, they invest less time and energy in their siblings, who are part of the family from which they are trying to establish autonomy. As a result, sibling relationships often become less intense, in both positive and negative feelings (Hetherington, Henderson, & Reiss, 1999; Kim et al., 2006).

Despite a drop in companionship, attachment between siblings, like closeness to parents, remains strong for most young people. Overall, siblings who established a positive bond in childhood continue to display greater affection and caring, which contribute to more favorable adolescent adjustment (Kim et al., 2007; Samek & Rueter, 2011). Older siblings frequently offer useful advice as their younger teenage brothers and sisters face challenges in romantic relationships, schoolwork, and decisions about the future. Consistent with the high value girls place on emotional closeness, sisters report greater intimacy with their siblings than brothers do, and sister–sister pairings tend to be the closest (Kim et al., 2006). Culture also influences quality of sibling relationships. In one study, Mexican-American adolescents who expressed a strong Mexican cultural orientation resolved sibling conflicts more cooperatively—compromising rather than controlling or confronting—than did those more oriented toward U.S. individualistic values (Killoren, Thayer, & Updegraff, 2008).

Sibling interaction at adolescence continues to be affected by other relationships, and vice versa. Teenagers whose parents are warm and supportive and who have a history of caring friendships have more positive sibling ties (Bussell et al., 1999; Kramer & Kowal, 2005). And in bidirectional fashion, warm adolescent sibling relationships contribute to more gratifying friendships (Yeh & Lempers, 2004). Finally, mild sibling differences in perceived parental affection no longer trigger jealousy but, instead, predict greater sibling warmth (Feinberg et al., 2003). Perhaps adolescents interpret a unique relationship with parents, as long as it is generally accepting, as a gratifying sign of their own individuality.

One-Child Families

Although sibling relationships bring many benefits, they are not essential for healthy development. Contrary to popular belief, only children are not spoiled, and in some respects, they are advantaged. U.S. children growing up in one-child and multichild families do not differ in self-rated personality traits (Mottus, Indus, & Allik, 2008). And compared to children with siblings, only children are higher in self-esteem and achievement motivation, do better in school, and attain higher levels of education. One reason may be that only children have somewhat closer relationships with parents, who may exert more pressure for mastery and accomplishment (Falbo, 1992). Furthermore, only children have just as many close, high-quality friendships as children with siblings. However, they tend to be less well-accepted in the peer group, perhaps because they have not had opportunities to learn effective conflict-resolution strategies through sibling interactions (Kitzmann, Cohen, & Lockwood, 2002).

Favorable development also characterizes only children in China, where a one-child family policy has been strictly enforced in urban areas for more than three decades to control population growth (Yang, 2008). Compared with agemates who have siblings, Chinese only children are advanced in cognitive development and academic achievement. They also

Limiting family size has been a national policy in the People's Republic of China for more than three decades. In urban areas, the majority of couples have no more than one child.

feel more emotionally secure, perhaps because government disapproval promotes tension in families with more than one child (Falbo & Poston, 1993; Jiao, Ji, & Jing, 1996; Yang et al., 1995). Chinese mothers usually ensure that their children have regular contact with first cousins (who are considered siblings). Perhaps as a result, Chinese only children do not differ from agemates with siblings in social skills and peer acceptance (Hart, Newell, & Olsen, 2003). The next generation of Chinese only children, however, will have no first cousins.

China's birth rate, at 1.5 per woman overall and .7 in its largest cities, is now lower than that of many developed nations. As a result, its elderly population is rapidly increasing while its working-age population has leveled off—an imbalance that threatens the country's economic progress. And because sons are more highly valued than daughters, the policy has resulted in an epidemic of abortions of female fetuses and abandonment of girl babies, yielding a vastly skewed population sex ratio (130 male births for every 100 female births) that jeopardizes social stability (Zhu & Hesketh, 2009). Consequently, China is considering relaxing the one-child policy, but it is now so culturally ingrained that couples say they would not have a second child, even if offered the opportunity (LaFraniere, 2011).

Adoptive Families

Adults who are infertile, who are likely to pass along a genetic disorder, or who are older and single but want a family are turning to adoption in increasing numbers. Those who have children by birth, too, sometimes choose to expand their families through adoption. Adoption agencies try to ensure a good fit by seeking parents of the same ethnic and religious background as the child and, where possible, choosing parents who are the same age as typical biological parents. Because the availability of healthy babies has declined (fewer young unwed mothers give up their babies than in the past), more people in North America and Western Europe are adopting from other countries or accepting children who are past infancy or who have known developmental problems (Schweiger & O'Brien, 2005).

Adopted children and adolescents—whether or not they were born in their adoptive parents' country—tend to have more learning and emotional difficulties than other children, a difference that increases with the child's age at time of adoption (Nickman et al., 2005; van IJzendoorn, Juffer, & Poelhuis, 2005; Verhulst, 2008). And whereas children adopted prior to their first birthday are as securely attached to their parents as nonadopted children are, those adopted later show higher rates of attachment insecurity (van den Dries et al., 2009).

Various explanations exist for adoptees' more problematic childhoods. The biological mother may have been unable to care for the child because of problems believed to be partly genetic, such as alcoholism or severe depression, and may have passed this tendency to her offspring. Or perhaps she experienced stress, poor diet, or inadequate medical care during pregnancy. Furthermore, children adopted after infancy are more likely than their nonadopted peers to have a preadoptive history of conflict-ridden family relationships, lack of parental affection, neglect and abuse, or deprived institutional rearing. Finally, adoptive parents and children, who are genetically unrelated, are less alike in intelligence and personality than are biological relatives—differences that may threaten family harmony.

Through family involvement in events like this Chinese Culture Day celebration, these parents increase the likelihood that their adopted children will develop identities that are a healthy blend of their birth and rearing backgrounds.

XINHUA/LANDOV

Despite these risks, most adopted children fare well, and those with preexisting problems usually make rapid progress (Arcus & Chambers, 2008; Bimmel et al., 2003). In a study of internationally adopted children in the Netherlands, sensitive maternal care and secure attachment in infancy predicted cognitive and social competence at age 7 (Stams, Juffer, & van IJzendoorn, 2002). And children with troubled family histories who are adopted at older ages generally improve in feelings of trust and affection for their adoptive parents, as they come to feel loved and supported (Veríssimo & Salvaterra, 2006).

By adolescence, adoptees' lives are often complicated by unresolved curiosity about their roots. Some have difficulty accepting the possibility that they may never know their birth parents. Others worry about what they would do if their birth parents suddenly reappeared. Adopted teenagers also face a more challenging process of defining themselves as they try to integrate aspects of their birth family and their adoptive family into their emerging identity.

Nevertheless, most adoptees appear well-adjusted as adults. When parents have been warm, open, and supportive in their communication about adoption, their children typically forge a positive sense of self (Brodzinsky, 2011). And as long as their parents took steps to help them learn about their heritage, young adults who were adopted into a different ethnic group or culture usually develop identities that are healthy blends of their birth and rearing backgrounds (Nickman et al., 2005; Thomas & Tessler, 2007).

Clearly, adoption is a satisfying family alternative for most parents and children who experience it. Good outcomes can be promoted by careful pairing of children with parents and provision of guidance to adoptive families by well-trained social service professionals.

Gay and Lesbian Families

According to recent estimates, about 20 to 35 percent of lesbian couples and 5 to 15 percent of gay couples are parents, most through previous heterosexual marriages, some through adoption, and a growing number through reproductive technologies (Gates et al., 2007; Goldberg, 2010; Patterson & Riskind, 2010). These figures underreport actual numbers, as many gay and lesbian parents are reluctant to disclose their identities. In the past, because of laws assuming that homosexuals could not be adequate parents, those who divorced a heterosexual partner lost custody of their children. Today, some U.S. states hold that sexual orientation in itself is irrelevant to custody. A few U.S. states, however, ban gay and lesbian couples from adopting children. Among other countries, gay and lesbian adoptions are legal in Argentina, Belgium, Brazil, Canada, Iceland, Mexico, the Netherlands, Norway, South Africa, Spain, Sweden, the United Kingdom, and Uruguay.

Most research on homosexual families is limited to volunteer samples. Findings indicate that gay and lesbian parents are as committed to and effective at child rearing as heterosexual parents and sometimes more so (Bos, van Balen, & van den Boom, 2007; Tasker, 2005). Also, whether born to or adopted by their parents or conceived through donor insemination, the children of homosexuals did not differ from the children of heterosexuals in mental health, peer relations, or gender-role behavior (Allen & Burrell, 1996; Bos & Sandfort, 2010; Farr, Forssell, & Patterson, 2010; Goldberg, 2010). Two additional studies, which surmounted the potential bias associated with a volunteer sample by including all lesbian-mother families who had conceived children at a fertility clinic, also reported that children were developing favorably (Brewaeys et al., 1997; Chan, Raboy, & Patterson, 1998). Likewise, among participants drawn from a representative sample of British mothers and their 7-year-olds, children reared in lesbian-mother families did not differ from children reared in heterosexual families in adjustment and gender-role preferences (Golombok et al., 2003).

© CREATAS IMAGES/JUPITER IMAGES/GETTY IMAGES

Gay and lesbian parents are as committed to and effective at child rearing as heterosexual parents. Their children are well-adjusted, and the large majority develop a heterosexual orientation.

Furthermore, children of gay and lesbian parents are similar to other children in sexual orientation: The large majority are heterosexual (Tasker, 2005). But some evidence suggests that more adolescents from homosexual families experiment for a time with partners of both sexes, perhaps as a result of being reared in families and communities especially tolerant of nonconformity and difference (Bos, van Balen, & van den Boom, 2004; Golombok & Tasker, 1996; Stacey & Biblarz, 2001). In support of this view, a Dutch investigation found that 8- to 12-year-old children of lesbian parents felt slightly less parental pressure to conform to gender roles than did children of heterosexual parents. The two groups were similar in other aspects of gender identity (gender typicality and gender contentedness, see page 550 in Chapter 13). At the same time, the children of lesbian parents reported greater sexual questioning—less certainty about future heterosexual attractions and relationships, though the group difference was mild (see Figure 14.3 on page 590) (Bos & Sandfort, 2010).

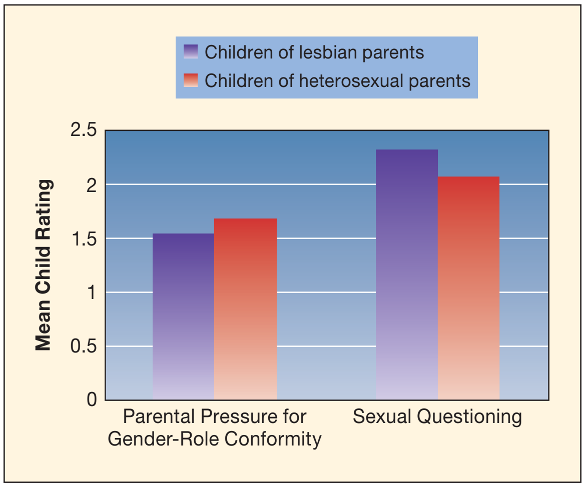

FIGURE 14.3 Reports of parental pressure for gender-role conformity and of sexual questioning by 8- to 12-year-olds of lesbian and heterosexual parents. Compared with children of heterosexual parents, children of lesbian parents rated parental pressure slightly lower and sexual questioning higher. Neither group expressed strong parental pressure or sexual questioning (participants rated each on a 4-point scale, and mean ratings ranged from 1.5 to 2.3). (Adapted from Bos & Sandfort, 2010.)

A major concern of gay and lesbian parents is that their children will be stigmatized by their parents' sexual orientation. Most studies indicate that incidents of teasing and bullying are rare because parents and children carefully manage the information they reveal to others (Tasker, 2005). But in an Australian study, even though most third to tenth graders were guarded about discussing their parents' relationship with peers, nearly half reported harassment (Ray & Gregory, 2001). Overall, children of gay and lesbian parents can be distinguished from other children mainly by issues related to living in a nonsupportive society.

Never-Married Single-Parent Families

Over the past several decades, births to unmarried mothers in industrialized nations have increased dramatically. Today, about 40 percent of U.S. births are to single mothers, more than double the percentage in 1980. Whereas teenage parenthood has recently declined (see page 217 in Chapter 5), unwed motherhood among women in their twenties and older has risen, especially among those in their thirties and forties in high-status occupations (U.S. Census Bureau, 2011b). But these higher-SES, older single mothers are still few in number, and little is known about their children's development.

In the United States, African-American young women make up the largest group of never-married parents. About 64 percent of births to black mothers in their twenties are to women without a partner, compared with 28 percent of births to white women (U.S. Census Bureau, 2011b). African-American women postpone marriage more and childbirth less than women in other U.S. ethnic groups. Job loss, persistent unemployment, and consequent inability of many black men to support a family have contributed to the number of African-American never-married, single-mother families.

Never-married African-American mothers tap the extended family, especially their own mothers and sometimes male relatives, for help in rearing their children (Gasden, 1999; Jayakody & Kalil, 2002). For about one-third, marriage—not necessarily to the child's biological father—occurs within nine years after birth of the first child (Wu, Bumpass, & Musick, 2001). These couples function much like other first-marriage parents. Their children are often unaware that the father is a stepfather, and parents do not report the child-rearing difficulties usually associated with remarriage that we will discuss shortly (Ganong & Coleman, 1994).

Still, for low-SES women, never-married parenthood generally increases financial hardship. Nearly 50 percent of white mothers and 60 percent of black mothers have a second child while unmarried. And they are far less likely than divorced mothers to receive paternal child support payments. Consequently, many children in single-mother homes display adjustment problems associated with economic adversity (Kotchick, Dorsey, & Heller, 2005). Furthermore, children of never-married mothers who lack a father's consistent warmth and involvement show less favorable cognitive development and engage in more antisocial behavior than children in low-SES, first-marriage families (Waldfogel, Craigie, & Brooks-Gunn, 2010). But marriage to the child's biological father benefits children only when the father is a reliable source of economic and emotional support. For example, when a mother pairs up with an antisocial father, her child is at far greater risk for conduct problems than if she had reared the child alone (Jaffee et al., 2003).

Over time, most unwed fathers—who usually have no more than a modest education and are doing poorly financially—spend less and less time with their children (Lerman, 2010). Strengthening social support, education, and employment opportunities for low-SES parents would greatly enhance the well-being of unmarried mothers and their children.

Divorce

Between 1960 and 1985, divorce rates in Western nations rose dramatically before stabilizing in most countries. The United States has experienced a decline in divorces over the past decade, largely due to a rise in age at first marriage (Amato & Dorius, 2010). Nevertheless, the United States continues to have the highest divorce rate in the world (see Figure 14.4). Of the 45 percent of American marriages that end in divorce, half involve children. At any given time, one-fourth of U.S. children live in single-parent households. Although most reside with their mothers, the percentage in father-headed households has increased steadily, to about 12 percent (Federal Interagency Forum on Child and Family Statistics, 2011).

Children of divorce spend an average of five years in a single-parent home—almost a third of childhood. For many, divorce leads to new family relationships. About two-thirds of divorced parents marry again. Half of their children eventually experience a third major change—the end of their parents' second marriage (Hetherington & Kelly, 2002).

These figures reveal that divorce is not a single event in the lives of parents and children. Instead, it is a transition that leads to a variety of new living arrangements, accompanied by changes in housing, income, and family roles and responsibilities. Since the 1960s, many studies have reported that marital breakup is stressful for children. But research also reveals great individual differences (Hetherington, 2003). How well children fare depends on many factors: the custodial parent's psychological health, the child's characteristics, and social supports within the family and surrounding community.

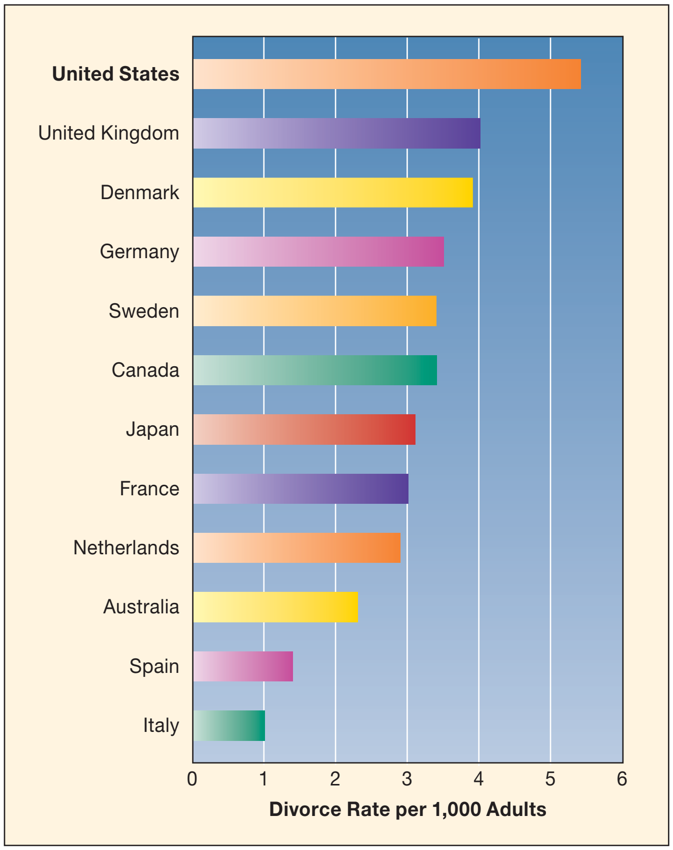

FIGURE 14.4 **Divorce rates in 12 industrialized nations.** The U.S. divorce rate is the highest in the industrialized world, far exceeding divorce rates in other countries. (Adapted from U.S. Census Bureau, 2011b.)

Immediate Consequences Family conflict often rises around the time of divorce as parents try to settle disputes over children and possessions. Once one parent moves out, additional events threaten supportive interactions between parents and children. Mother-headed households typically experience a sharp drop in income. In the United States, 27 percent of divorced mothers with young children live in poverty and many more are low-income, getting less than the full amount of child support from the absent father or none at all (Grall, 2009). They often have to move to lower-cost housing, reducing supportive ties to neighbors and friends.

The transition from marriage to divorce typically leads to high maternal stress, depression, and anxiety and to a disorganized family situation. Declines in well-being are greatest for mothers of young children (Williams & Dunne-Bryant, 2006). Predictable events and routines—meals and bedtimes, household chores, and joint parent–child activities—usually disintegrate. As children react with distress and anger to their less secure home lives, discipline may become harsh and inconsistent. Contact with noncustodial fathers decreases over time (Hetherington & Kelly, 2002). Fathers who see their children only occasionally are inclined to be permissive and indulgent, making the mother's task of managing the child even more difficult.

The more parents argue and fail to provide children with warmth, involvement, and consistent guidance, the poorer children's adjustment. About 20 to 25 percent of children in divorced families display severe problems, compared with about 10 percent in nondivorced families (Lansford, 2009; Noller et al., 2008). At the same time, reactions vary with children's age, temperament, and sex.

Children's Age. Preschool and early school-age children often blame themselves for a marital breakup and fear that both parents may abandon them (Lansford et al., 2006a). Hence, they are more likely to display both anxious, fearful and angry, defiant reactions than older children and adolescents with the cognitive maturity to understand that they are not responsible for their parents' divorce.

Still, many school-age and adolescent youngsters also react strongly, experiencing depressed mood, declining in school performance, becoming unruly, and escaping into undesirable peer activities, such as running away, truancy, and early sexual activity, particularly

When parents divorce, young children often blame themselves and respond with both fear and anger. This father's soothing words help his daughter understand that she is not responsible for the marital breakup.

when family conflict is high and parental supervision is low (D'Onofrio et al., 2006; Lansford et al., 2006a). Some older children—especially the oldest child in the family—display more mature behavior, willingly taking on family and household tasks, care of younger siblings, and emotional support of a depressed, anxious mother. But if these demands are too great, these children may eventually become resentful, withdraw from the family, and engage in angry, acting-out behavior (Hetherington, 1999).

Children's Temperament and Sex. Exposure to stressful life events and inadequate parenting magnifies the problems of temperamentally difficult children (Lengua et al., 2000). Easy children, who are less often targets of parental anger, also cope better with adversity.

These findings help explain sex differences in response to divorce. Girls sometimes respond with internalizing reactions such as crying, self-criticism, and withdrawal. More often, children of both sexes show demanding, attention-getting behavior. These declines in psychological well-being contribute to the poorer academic achievement of children of divorce (Potter, 2010). But in mother-custody families, boys are at slightly greater risk for serious adjustment problems (Amato, 2001, 2010). Recall from Chapter 13 that boys are more active and noncompliant—behaviors that increase with exposure to parental conflict and inconsistent discipline. Research reveals that long before the marital breakup, sons of divorcing couples display higher rates of impulsivity, defiance, and aggression—behaviors that may have been caused by their parents' marital problems while also contributing to them (Hetherington, 1999; Shaw, Winslow, & Flanagan, 1999; Strohschein, 2005). As a result, more boys enter the period of turmoil surrounding divorce with reduced capacity to cope with family stress.

Perhaps because their behavior is more unruly, boys of divorcing parents tend to receive less emotional support from mothers, teachers, and peers. Furthermore, the cycles of coercive interaction between angry, defiant sons and their divorced mothers soon spread to sibling relations, compounding adjustment difficulties (Hetherington & Kelly, 2002; Sheehan et al., 2004). After divorce, children who are challenging to rear generally get worse.

Long-Term Consequences Most children show improved adjustment by two years after divorce. Yet overall, children and adolescents of divorced parents continue to score slightly lower than children of continuously married parents in academic achievement, self-esteem, social competence, and emotional and behavior problems (Amato, 2001; Lansford, 2009). Children with difficult temperaments who were entrenched in family conflict are more likely to drop out of school, to be depressed, and to engage in antisocial behavior in adolescence. And divorce is linked to problems with adolescent sexuality and development of intimate ties. Young people who experienced parental divorce—especially more than once—display higher rates of early sexual activity and adolescent parenthood (Wolfinger, 2000). Some experience other lasting difficulties—reduced educational attainment, troubled romantic relationships and marriages, divorce in adulthood, and unsatisfying parent–child relationships (Amato, 2006, 2010; Lansford, 2009). Thus, divorce can have consequences for subsequent generations.

The overriding factor in positive adjustment following divorce is effective parenting—how well the custodial parent handles stress and shields the child from family conflict, and the extent to which each parent uses authoritative child rearing (Leon, 2003; Wolchik et al., 2000). Where the custodial parent is the mother, contact with fathers is also important. In the United States, paternal contact has risen over the past three decades, with about one-third of children today experiencing at least weekly visits (Amato & Dorius, 2010).

The more paternal contact and the warmer the father–child relationship, the less children of divorce react with defiance and aggression (Dunn et al., 2004). For girls, a good father–child relationship protects against early sexual activity and unhappy romantic involvements (Clarke-Stewart & Hayward, 1996; McLanahan, 1999). High father–child contact, however, occurs more often in families where the mother–child relationship is positive and divorced parents are courteous and cooperative (Dunn, 2004a).

LOOK and LISTEN

Discuss with a few of your contemporaries who experienced parental divorce in childhood their view of its long-term impact. Ask them to address factors they see as having fostered or impeded their adjustment to the divorce.

Several studies report that outcomes for sons are better when the father is the custodial parent (Clarke-Stewart & Hayward, 1996; McLanahan, 1999). Fathers' greater economic security and image of authority seem to help them engage in effective parenting with sons. And boys in father-custody families may benefit from greater involvement of both parents because noncustodial mothers participate more in their children's lives than do noncustodial fathers.

Although divorce is painful for children, remaining in an intact but high-conflict family is worse than making the transition to a low-conflict single-parent household (Greene et al., 2003; Strohschein, 2005). However, more parents today are divorcing because they are moderately (rather than extremely) dissatisfied with their relationship. Research suggests that children in these low-discord homes are especially puzzled and upset. Perhaps these youngsters' inability to understand the marital breakup and grieve over the loss of a seemingly happy home life explain why the adjustment problems of children of divorce have intensified over time (Amato, 2001; Lansford, 2009).

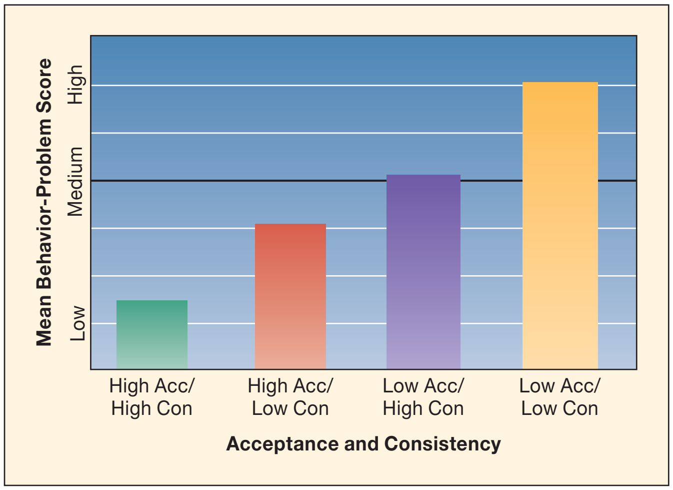

FIGURE 14.5 **Relationship of child-rearing styles to children's adjustment following divorce.** High parental acceptance and consistency in discipline are associated with a low level of behavior problems. As child rearing diminished in quality, behavior problems increased. When both parental acceptance and consistency in discipline were low, behavior problems were severe. All 8- to 15-year-olds in this study had experienced a highly stressful divorce. (Adapted from Wolchik et al., 2000.)

Regardless of the extent of their friction, parents who set aside their disagreements and engage in effective coparenting greatly improve their children's chances of growing up competent, stable, and happy. As Figure 14.5 shows, in a study of 8- to 15-year-olds, young people who experienced both high parental acceptance and high consistency of discipline had the lowest levels of adjustment problems (Wolchik et al., 2000). Caring extended-family members, teachers, siblings, and friends also reduce the likelihood that divorce will result in long-term difficulties (Hetherington, 2003; Lussier et al., 2002).

Divorce Mediation, Joint Custody, and Child Support

Awareness that divorce is highly stressful for parents and children has led to community-based services aimed at helping them through this difficult time. One such service is *divorce mediation,* a series of meetings between divorcing couples and a trained professional aimed at reducing family conflict, including legal battles over property division and child custody. Research reveals that mediation increases out-of-court settlements, effective coparenting, sustained involvement of both parents in their children's lives, and parents' and children's feelings of well-being (Douglas, 2006; Emery, Sbarra, & Grover, 2005). In one study, parents who had resolved disputes through mediation, as opposed to an adversarial legal process, were still more involved in their children's lives 12 years later (Emery, Sbarra, & Grover, 2005).

To further encourage parents to resolve their disputes, parent education programs are becoming common. During several sessions, professionals teach parents about the positive impact of constructive conflict resolution and of respectful, cooperative coparenting on children's well-being (Braver et al., 2005; Cookston et al., 2006; Wolchik et al., 2002). Because of the demonstrated impact of parent education on parental cooperation, courts in many U.S. states may require parents to attend a program.

Joint custody, which grants each parent an equal say in important decisions about the child's upbringing, is becoming increasingly common. Children usually reside with one parent and see the other on a fixed schedule, similar to the typical sole-custody situation. In other cases, parents share physical custody, and children move between homes and sometimes between schools and peer groups. These transitions can be especially hard on some children. Joint-custody parents report little conflict—fortunately so, since the success of the arrangement depends on coparenting. And their children, regardless of living arrangements, tend to be better-adjusted than their counterparts in sole maternal-custody homes (Bauserman, 2002).

Finally, many single-parent families depend on child support from the absent parent to relieve financial strain. All U.S. states have procedures for withholding wages from parents who fail to make these payments. Although child support is usually not enough to lift a single-parent family out of poverty, it can ease its burdens substantially. Noncustodial fathers who have generous visitation schedules and see their children often are more likely to pay child support regularly (Amato & Sobolewski, 2004). And increases in contact with the child

APPLYING WHAT WE KNOW

Helping Children Adjust to Their Parents' Divorce

SUGGESTION	EXPLANATION
Shield children from conflict.	Witnessing intense parental conflict is very damaging to children. If one parent insists on expressing hostility, children fare better if the other parent does not respond in kind.
Provide children with as much continuity, familiarity, and predictability as possible.	Children adjust better during the period surrounding divorce when their lives have some stability—for example, the same school, bedroom, babysitter, playmates, and daily schedule.
Explain the divorce and tell children what to expect.	Children are more likely to develop fears of abandonment if they are not prepared for their parents' separation. They should be told that their parents will not be living together anymore, which parent will be moving out, and when they will be able to see that parent. If possible, parents should explain the divorce together, providing a reason that each child can understand and assuring children that they are not to blame.
Emphasize the permanence of the divorce.	Fantasies of parents getting back together can prevent children from accepting the reality of their current life. Children should be told that the divorce is final and that they cannot change this fact.
Respond sympathetically to children's feelings.	Children need a supportive and understanding response to their feelings of sadness, fear, and anger. For children to adjust well, their painful emotions must be acknowledged, not denied or avoided.
Engage in authoritative parenting.	Parents who engage in authoritative parenting—providing affection and acceptance, reasonable demands for mature behavior, and consistent, rational discipline—greatly reduce their children's risk of maladjustment following divorce.
Promote a continuing relationship with both parents.	When parents disentangle their lingering hostility toward the former spouse from the child's need for a continuing relationship with the other parent, children adjust well. Grandparents and other extended-family members can help by not taking sides.

Source: Teyber, 2001.

and in child support over time predict better coparenting relationships (Hofferth, Forry, & Peters, 2010). Applying What We Know above summarizes ways to help children adjust to their parents' divorce.

Blended Families

Life in a single-parent family often is temporary. About 60 percent of divorced parents remarry within a few years. Others *cohabit,* or share a sexual relationship and a residence with a partner outside of marriage. Parent, stepparent, and children form a new family structure called the **blended,** or **reconstituted, family.** For some children, this expanded family network is positive, bringing greater adult attention. But most have more adjustment problems than children in stable, first-marriage families (Jeynes, 2007; Nicholson et al., 2008). Switching to stepparents' new rules and expectations can be stressful, and children often regard steprelatives as intruders. How well they adapt is, again, related to the overall quality of family functioning (Hetherington & Kelly, 2002). This depends on which parent forms a new relationship, the child's age and sex, and the complexity of blended-family relationships. As we will see, older children and girls seem to have the hardest time.

Mother–Stepfather Families Because mothers generally retain custody of children, the most common form of blended family is a mother–stepfather arrangement. Boys tend to adjust quickly, welcoming a stepfather who is warm, who refrains from exerting his authority too quickly, and who offers relief from coercive cycles of mother–son interaction. Mothers' friction with sons also declines as a result of greater economic security, another adult to share household tasks, and an end to loneliness (Visher, Visher, & Pasley, 2003).

Stepfathers who marry rather than cohabit are more involved in parenting, perhaps because men who choose to marry a mother with children are more interested in and skilled at child rearing (Hofferth & Anderson, 2003). Girls, however, often have difficulty with their custodial mother's remarriage. Stepfathers disrupt the close ties many girls have established with their mothers, and girls often react with sulky, resistant behavior (Bray, 1999).

But age affects these findings. Older school-age children and adolescents of both sexes display more irresponsible, acting-out behavior than their peers not in stepfamilies (Hetherington & Stanley-Hagan, 2000; Robertson, 2008). If parents are warmer and more involved with their biological children than with their stepchildren, older children are more likely to notice and challenge unfair treatment. And adolescents often view the new stepparent as a threat to their freedom, especially if they experienced little parental monitoring in the single-parent family. When teenagers have affectionate, cooperative relationships with their mothers, many develop good relationships with stepfathers following remarriage—a circumstance linked to more favorable adolescent well-being (King, 2009; Yuan & Hamilton, 2006).

Father–Stepmother Families Remarriage of noncustodial fathers often leads to reduced contact with their biological children, especially when fathers remarry quickly, before they have established postdivorce parent–child routines (Dunn, 2002; Juby et al., 2007). When fathers have custody, children typically react negatively to remarriage. One reason is that children living with fathers often start out with more problems. Perhaps the biological mother could no longer handle the difficult child (usually a boy), so the father and his new partner are faced with a youngster who has behavior problems. In other instances, the father has custody because of a very close relationship with the child, and his remarriage disrupts this bond (Buchanan, Maccoby, & Dornbusch, 1996).

Girls, especially, have a hard time getting along with their stepmothers, either because the remarriage threatens the girl's bond with her father or because she becomes entangled in loyalty conflicts between the two mother figures. But the longer children live in father–stepmother households, the closer they feel to their stepmothers and the more positive their interaction with them becomes (King, 2007). With time and patience, children of both genders benefit from the support of a second mother figure.

Support for Blended Families Parenting education and couples counseling can help parents and children adapt to the complexities of blended families. Effective approaches encourage stepparents to move into their new roles gradually by first building a warm relationship with the child, which makes more active parenting possible (Nicholson et al., 2008). Counselors can offer couples guidance in coparenting to limit loyalty conflicts and provide consistency in child rearing. And tempering parents' unrealistic expectations for children's rapid adjustment—by pointing out that building a unified blended family often takes years—makes it easier for families to endure the transition and succeed.

Unfortunately, the divorce rate for second marriages is even higher than that for first marriages. Parents with antisocial tendencies and poor child-rearing skills are particularly likely to have several divorces and remarriages. The more marital transitions children experience, the greater their adjustment difficulties (Amato, 2010). These families usually require prolonged, intensive therapy.

When stepparents build warm relationships with stepchildren before moving into their parenting role, they ease children's adjustment to life in a blended family.

Maternal Employment and Dual-Earner Families

Today, U.S. single and married mothers are in the labor market in nearly equal proportions, and more than three-fourths of those with school-age children are employed (U.S. Census Bureau, 2011b). In Chapter 10, we saw that the impact of maternal employment on early development depends on the quality of child care during parents' working hours, the continuing parent–child relationship, and fathers' participation in caregiving. The same is true in later years. In addition, the mother's work satisfaction has a bearing on how children fare.

© SIMON JARRATT/CORBIS

Employed mothers who enjoy their work while also valuing the parenting role tend to have children who show higher self-esteem, more positive family and peer relations, less gender-stereotyped beliefs, and better school performance.

Maternal Employment and Child Development When mothers enjoy their work and remain committed to parenting, children show favorable adjustment—higher self-esteem, more positive family and peer relations, less gender-stereotyped beliefs, and better grades in school. Girls, especially, profit from the image of female competence. Regardless of SES, daughters of employed mothers perceive women's roles as involving more freedom of choice and satisfaction and are more achievement- and career-oriented (Hoffman, 2000).

Parenting practices contribute to these benefits. Employed mothers who value their parenting role are more likely to use authoritative child rearing and coregulation (see page 577). Also, children in dual-earner households devote more daily hours to doing homework under parental guidance and participate more in household chores. And maternal employment often leads fathers—especially those who believe in the importance of the paternal role and who feel successful at rearing children—to take on greater child-care responsibilities (Jacobs & Kelley, 2006). Paternal involvement is associated with higher intelligence and achievement, more mature social behavior, greater gender-stereotype flexibility in childhood and adolescence, and generally better mental health in adulthood (Coltrane, 1996; Pleck & Masciadrelli, 2004).

But when employment places heavy demands on a mother's or a father's schedule or is stressful for other reasons, children are at risk for ineffective parenting. Working many hours or experiencing a negative workplace atmosphere is associated with reduced parental sensitivity, fewer joint parent–child activities, and poorer cognitive development throughout childhood and adolescence (Brooks-Gunn, Han, & Waldfogel, 2002; Bumpus, Crouter, & McHale, 2006; Strazdins et al., 2006). Negative consequences are magnified when low-SES mothers spend long days at low-paying, menial, or physically taxing jobs—conditions linked to maternal depression and harsh, inconsistent discipline (Raver, 2003). In contrast, part-time employment and flexible work schedules are associated with parents' enhanced satisfaction with family life and good adjustment in children and adolescents (Frederiksen-Goldsen & Sharlach, 2000; Hill et al., 2006). By preventing work–family life conflict, these arrangements help parents meet children's needs.

Support for Employed Parents and Their Families In dual-earner families, the father's willingness to share child-care responsibilities is a crucial factor. If he helps little or not at all, the mother carries a double load, at home and at work, leading to fatigue, distress, and little time and energy for children. Fortunately, compared to three decades ago, today's U.S. fathers are far more involved in child care (see page 483 in Chapter 10). But their increased participation has resulted in a growing number of fathers who also report work–family life conflict (Galinsky, Aumann, & Bond, 2009).

Employed parents need assistance from work settings and communities in their child-rearing roles. Part-time employment, flexible schedules, job sharing, and paid leave when children are ill help parents juggle the demands of work and child rearing. Equal pay and equal employment opportunities for women also are important. Because these policies enhance financial status and morale, they improve the way mothers feel and behave when they return home at the end of the working day.

Child Care

Over the past several decades, the number of young children in child care in the United States has steadily increased to more than 60 percent (U.S. Census Bureau, 2011b). Over half of 3- to 6-year-olds not yet in kindergarten are cared for in child-care centers, with the remainder in family child-care homes or looked after informally by a relative or their fathers. But nearly one-fourth of preschoolers, most from low-income families, experience several types of care at once, transitioning between two—and sometimes more than two—settings each day. In addition to a changing cast of caregivers, children in multiple care settings must cope with longer hours in child care (Federal Interagency Forum on Child and Family Statistics, 2011; NICHD Early Child Care Research Network, 2006).

With age, children typically shift from home-based to center care. Children of higher-income parents and children of very low-income parents are especially likely to be in center care. Many lower-income working parents rely on care by relatives because they are not eligible for public preschool or government-subsidized center child care (Bainbridge et al., 2005; Meyers et al., 2004).

Recall from Chapter 8 that early intervention can enhance the development of economically disadvantaged children. As noted in Chapters 1 and 10, however, much U.S. child care is of poor quality. Refer to Chapter 10, pages 441–442, for a discussion of the negative consequences of exposing infants and toddlers to substandard child care and to many weekly hours of child care. Preschoolers, as well, suffer when placed in poor-quality child care, especially for long hours, scoring lower in cognitive and social skills and higher in behavior problems (Belsky, 2006b; Lamb & Ahnert, 2006; NICHD Early Childhood Research Network, 2003b, 2006). Externalizing difficulties are especially likely to endure through middle childhood and into adolescence after extensive exposure to mediocre care (Belsky et al., 2007; Vandell et al., 2010). And when children experience the instability of several child-care settings, the emotional problems of temperamentally difficult preschoolers worsen considerably (De Schipper, van IJzendoorn, & Tavecchio, 2004; De Schipper et al., 2004).

In contrast, good child care enhances cognitive, language, and social development, especially for low-SES children—effects that persist into elementary school and, for academic achievement, into adolescence (Belsky et al., 2007; Burchinal, Vandergrift, & Pianta, 2010; NICHD Early Child Care Research Network, 2006; Vandell et al., 2010). In a study that followed 400 very low-income children over the preschool years, center-based care was more strongly associated with cognitive gains than were other child-care arrangements, probably because good-quality child-care centers are more likely to provide a systematic educational program. At the same time, better-quality experiences in all types of child care predicted modest improvements in cognitive, emotional, and social development (Loeb et al., 2004).

What are the ingredients of high-quality child care for preschoolers? Large-scale studies identify several important factors: group size (number of children in a single space), caregiver–child ratio, caregivers' educational preparation, and caregivers' personal commitment to learning about and caring for children. When these characteristics are favorable, adults are more verbally stimulating and sensitive to children's needs (Lamb & Ahnert, 2006).

Applying What We Know on page 598 summarizes characteristics of high-quality early childhood programs, based on standards devised by the U.S. National Association for the Education of Young Children. Unfortunately, much U.S. child care is substandard: too often staffed by underpaid adults without specialized educational preparation, overcrowded with children, and (in the case of family child care) unlicensed and therefore not monitored for quality. And child care is expensive: For U.S. families with just one preschooler, it consumes, on average, 29 percent of the typical earnings of a single mother and 10 percent of the earnings of a two-parent family (NACCRRA, 2010).

In contrast, in Australia and Western Europe, government-subsidized child care that meets rigorous standards is widely available, and caregivers are paid on the same salary scale as elementary school teachers (Waldfogel, 2001). Because the United States does not have national child-care policies, it lags behind other industrialized nations in supply, quality, and affordability of child care.

Self-Care

High-quality child care is vital for parents' peace of mind and children's well-being, even during middle childhood. An estimated 5 million 5- to 14-year-olds in the United States are **self-care children,** who regularly look after themselves for some period of time during after-school hours (Afterschool Alliance, 2009). As Figure 14.6 shows, self-care rises dramatically with age. It also increases with SES, perhaps because of the greater safety of higher-income neighborhoods. But when

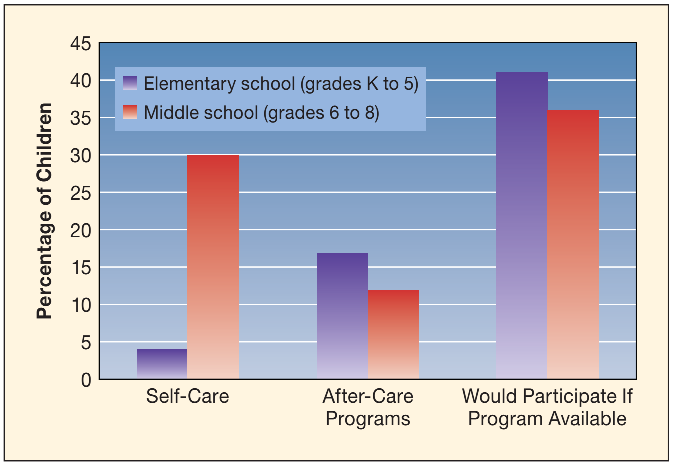

FIGURE 14.6 Prevalence of self-care and participation in after-care programs by U.S. elementary and middle-school students. A survey of a large, nationally representative sample of U.S. parents confirms that self-care rises sharply in middle school. Many parents say that if after-care programs were available in their neighborhoods, they would enroll their children. (From Afterschool Alliance, 2009.)

APPLYING WHAT WE KNOW

Signs of Developmentally Appropriate Early Childhood Programs

PROGRAM CHARACTERISTIC	SIGNS OF QUALITY
Physical setting	Indoor environment is clean, in good repair, and well-ventilated. Classroom space is divided into richly equipped activity areas, including make-believe play, blocks, science, math, games and puzzles, books, art, and music. Fenced outdoor play space is equipped with swings, climbing equipment, tricycles, and sandbox.
Group size	In preschools and child-care centers, group size is no greater than 18 to 20 children with two teachers.
Caregiver–child ratio	In preschools and child-care centers, teacher is responsible for no more than 8 to 10 children. In family child-care homes, caregiver is responsible for no more than 6 children.
Daily activities	Children select many of their own activities and learn through experiences relevant to their own lives, mainly in small groups or individually. Teachers facilitate children's involvement, accept individual differences, and adjust expectations to children's developing capacities.
Interactions between adults and children	Teachers move among groups and individuals, asking questions, offering suggestions, and adding more complex ideas. Teachers use positive guidance techniques, such as modeling and encouraging expected behavior and redirecting children to more acceptable activities.
Teacher qualifications	Teachers have college-level specialized preparation in early childhood development, early childhood education, or a related field.
Relationships with parents	Parents are encouraged to observe and participate. Teachers talk frequently with parents about children's behavior and development.
Licensing and accreditation	Child-care setting, whether a center or a home, is licensed by the state. Voluntary accreditation by the NAEYC Academy for Early Childhood Program Accreditation *(www.naeyc.org/accreditation)* or the National Association for Family Child Care *(www.nafcc.org)* is evidence of an especially high-quality program.

Sources: Copple & Bredekamp, 2009.

lower-SES parents lack alternatives to self-care, their children spend more hours on their own (Casper & Smith, 2002).

Some studies report that self-care children suffer from low self-esteem, antisocial behavior, poor academic achievement, and fearfulness. Others show no such effects. Children's maturity and the way they spend their time seem to explain these contradictions. Among younger school-age children, those who spend more hours alone have more adjustment difficulties (Vandell & Posner, 1999). As children become old enough to look after themselves, those who have a history of authoritative child rearing, are monitored by parental telephone calls, and have regular after-school chores appear responsible and well-adjusted. In contrast, children left to their own devices are more likely to bend to peer pressures and engage in antisocial behavior (Coley, Morris, & Hernandez, 2004; Vandell et al., 2006).

© JIM WEST/ALAMY

High-quality after-school programs with enrichment activities yield academic and social benefits for low-SES school-age children.

Before age 8 or 9, most children need supervision because they are not yet competent to handle emergencies (Galambos & Maggs, 1991). Also, throughout middle childhood and early adolescence, attending after-school programs with well-trained staffs, generous adult–child ratios, and skill-building activities is linked to good school performance and emotional and social adjustment (Durlak & Weissberg, 2007; Granger, 2008). Low-SES children who participate in "after-care" programs offering academic assistance and enrichment activities (scouting, music and art lessons, clubs) show special benefits. They exceed their self-care counterparts in classroom work habits, academic achievement, and prosocial behavior and display fewer behavior problems (Lauer et al., 2006; Vandell et al., 2006).

Unfortunately, good after-care is in especially short supply in low-income neighborhoods, and children from the poorest families are least likely to participate in enrichment activities (Afterschool Alliance, 2009; Dearing et al., 2009). A survey of a large, nationally representative sample of U.S. parents revealed if programs were available in their neighborhoods, many would enroll their children (refer again to Figure 14.6). A special need exists for well-planned programs in poverty-stricken areas—ones that provide safe environments, warm relationships with adults, and enjoyable, goal-oriented activities.

LOOK and LISTEN

In your community, what school-based after-care programs are available, and how plentiful are they in low-income neighborhoods? If possible, visit a program, observing for supportive adult involvement, academic assistance, and enrichment activities.

ASK YOURSELF

Review ■ Describe and explain changes in sibling relationships from early childhood to adolescence. What can parents do to promote positive sibling ties?

Connect ■ Review research on resilience in Chapter 1 (see pages 10–11). Are factors that foster resilience similar to those that promote favorable adjustment to parental divorce and blended families? Explain.

Apply ■ Steve and Marissa are in the midst of an acrimonious divorce. Their 9-year-old son, Dennis, has become hostile and defiant. How can Steve and Marissa help Dennis adjust?

Reflect ■ What after-school child-care arrangements did you experience in elementary school? How do you think they influenced your development?

Vulnerable Families: Child Maltreatment

▶ Discuss the origins of child maltreatment, its consequences for development, and prevention strategies.

Throughout our discussion of family transitions, we have considered many factors, both within and outside the family, that contribute to parents' capacity to be warm, consistent, and appropriately demanding. As we turn to the topic of child maltreatment, we will see that when these vital supports for effective child rearing break down, children—and their parents—can suffer terribly.

Incidence and Definitions

Child maltreatment is as old as human history, but only recently has the problem been widely acknowledged and research aimed at understanding it. Perhaps public concern has increased because child maltreatment is especially common in large industrialized nations. In the most recently reported year, about 700,000 U.S. children (10 out of every 1,000) were identified as victims (U.S. Department of Health and Human Services, 2010b). Because most cases go unreported, the true figures are much higher.

Child maltreatment takes the following forms:

- *Physical abuse.* Assaults, such as kicking, biting, shaking, punching, or stabbing, that inflict physical injury
- *Sexual abuse.* Fondling, intercourse, exhibitionism, commercial exploitation through prostitution or production of pornography, and other forms of sexual exploitation
- *Neglect.* Failure to meet a child's basic needs for food, clothing, medical attention, education, or supervision
- *Emotional abuse.* Acts that could cause serious mental or behavioral disorders, including social isolation, repeated unreasonable demands, ridicule, humiliation, intimidation, or terrorizing

Neglect accounts for 78 percent of reported cases, physical abuse for 18 percent, emotional abuse for 9 percent, and sexual abuse for 10 percent (U.S. Department of Health and Human

Services, 2010b). These figures sum to more than 100 percent because a single case report can include more than one form. Child welfare authority investigations suggest that from 45 to 90 percent of cases involve multiple types of maltreatment—on average, three kinds (Finkelhor et al., 2005).

Parents commit more than 80 percent of abusive incidents. Other relatives account for about 5 percent. The remainder are perpetrated by parents' unmarried partners, school officials, camp counselors, and other adults. Mothers engage in neglect more often than fathers, whereas fathers engage in sexual abuse more often than mothers. Maternal and paternal rates of physical and emotional abuse are fairly similar. And in an especially heartrending 18 percent of cases, parents jointly commit the abusive acts. Infants and young preschoolers are at greatest risk for neglect, preschool and school-age children for physical, emotional, and sexual abuse. But each type occurs at every age (Trocomé & Wolfe, 2002; U.S. Department of Health and Human Services, 2010b).

Origins of Child Maltreatment

Early findings suggested that child maltreatment was rooted in adult psychological disturbance (Kempe et al., 1962). But although child maltreatment is more common among disturbed parents, it soon became clear that a single "abusive personality type" does not exist. Parents who were abused as children do not necessarily become abusers (Buchanan, 1996; Simons et al., 1991). And sometimes even "normal" parents harm their children!

For help in understanding child maltreatment, researchers turned to the social systems perspective on family functioning. They discovered that many interacting variables—at the family, community, and cultural levels—contribute. Table 14.3 summarizes factors associated with physical and emotional abuse and neglect. For a discussion of child sexual abuse, see the Social Issues: Health box on the following page.

The Family Within the family, children whose characteristics make them more challenging to rear are more likely to become targets of abuse. These include premature or very sick babies and children who are temperamentally difficult, are inattentive or overactive, or have other developmental problems. Child factors, however, only slightly increase the risk (Jaudes & Mackey-Bilaver, 2008; Sidebotham et al., 2003). Whether such children are maltreated largely depends on parents' characteristics.

Maltreating parents are less skillful than other parents in handling discipline confrontations and getting children to cooperate in working toward common goals. They also suffer from biased thinking about their child. For example, they often evaluate transgressions as worse than they are, attribute their baby's crying or their child's misdeeds to a stubborn or bad disposition, and feel powerless in parenting—perspectives that lead them to move quickly toward physical force (Bugental & Happaney, 2004; Crouch et al., 2008).

Once abuse begins, it quickly becomes part of a self-sustaining relationship. The small irritations to which abusive parents react—a fussy baby, a preschooler who knocks over her milk, or a child who will not mind immediately—soon become bigger ones. Then the harshness increases. By the preschool years, abusive and neglectful parents seldom interact with their children. When they do, they rarely express pleasure and affection; the communication is almost always negative (Wolfe, 2005).

Most parents have enough self-control not to respond with abuse to their children's misbehavior or developmental problems. Other factors combine with these conditions to prompt an extreme response. Unmanageable parental stress is strongly associated with maltreatment. Abusive parents respond to stressful

TABLE 14.3 Factors Related to Child Maltreatment

FACTOR	DESCRIPTION
Parent characteristics	Psychological disturbance; alcohol and drug abuse; history of abuse as a child; belief in harsh physical discipline; desire to satisfy unmet emotional needs through the child; unreasonable expectations for child behavior; young age (most under 30); low educational level
Child characteristics	Premature or very sick baby; difficult temperament; inattentiveness and overactivity; other developmental problems
Family characteristics	Low income or poverty; homelessness; marital instability; social isolation; partner abuse; frequent moves; large family with closely spaced children; overcrowded living conditions; disorganized household; lack of steady employment; other signs of high life stress
Community	Characterized by violence and social isolation; few parks, child-care centers, preschool programs, recreation centers, or religious institutions to serve as family supports
Culture	Approval of physical force and violence as ways to solve problems

SOCIAL ISSUES: HEALTH

Child Sexual Abuse

Until recently, child sexual abuse was considered rare, and adults often dismissed children's claims of abuse. In the 1970s, efforts by professionals and media attention led to recognition of child sexual abuse as a serious and widespread problem. About 66,000 cases in the United States were confirmed in the most recently reported year (U.S. Department of Health and Human Services, 2010b). But this figure greatly underestimates the extent of sexual abuse, since most victims either delay disclosure for a long time or remain silent (London et al., 2005).

Characteristics of Abusers and Victims

Sexual abuse is committed against children of both sexes, but more often against girls. Most cases are reported in middle childhood, but sexual abuse also occurs at younger and older ages. For some victims, abuse begins early in life and continues for many years (Hoch-Espada, Ryan, & Deblinger, 2006; Trickett & Putnam, 1998).

Typically, the abuser is a male, either a parent or someone the parent knows well—a father, stepfather, or live-in boyfriend or, somewhat less often, an uncle or older brother. But in about 25 percent of cases, mothers are the offenders, more often with sons (Boroughs, 2004). If the abuser is a nonrelative, the person is usually someone the child has come to know and trust. However, the Internet and mobile phones have become avenues through which other adults commit sexual abuse—for example, by exposing children and adolescents to pornography and online sexual advances as a way of "grooming" them for sexual acts offline (Wolak et al., 2008).

Abusers make the child comply in a variety of distasteful ways, including deception, bribery, verbal intimidation, and physical force. You may wonder how any adult—especially a parent or close relative—could violate a child sexually. Many offenders deny their own responsibility, blaming the abuse on the willing participation of a seductive youngster. Yet children are not capable of making a deliberate, informed decision to enter into a sexual relationship! Even older children and adolescents are not free to say yes or no. Rather, the responsibility lies with abusers, who tend to have characteristics that predispose them toward sexual exploitation of children. They have great difficulty controlling their impulses and may suffer from psychological disorders, including alcohol and drug abuse. Often they pick out children who are unlikely to defend themselves or to be believed—those who are physically weak, emotionally deprived, socially isolated, or affected by disabilities (Bolen, 2001).

Reported cases of child sexual abuse are linked to poverty, marital instability, and resulting weakening of family ties. Children who live in homes with a constantly changing cast of characters—repeated marriages, separations, and new partners—are especially vulnerable. But children in economically advantaged, stable families are also victims, although their abuse is more likely to escape detection (Putnam, 2003).

CAMPAIGN AGAINST CHILD ABUSE & EXPLOITATION
S T O P !
CAMPAIGN AGAINST CHILD ABUSE AND SEXUAL EXPLOITATION
STAY SAFE

Children in Hyderabad, India, participate in a "Stay Safe" campaign against child abuse and sexual exploitation—part of a global effort to prevent all forms of abuse.

Consequences of Sexual Abuse

The adjustment problems of child sexual abuse victims—including anxiety, depression, low self-esteem, mistrust of adults, and anger and hostility—are often severe and can persist for years after the abusive episodes. Younger children frequently react with sleep difficulties, loss of appetite, and generalized fearfulness. Adolescents may run away and show suicidal reactions, substance abuse, and delinquency. At all ages, persistent abuse accompanied by force, violence, and a close relationship to the perpetrator (incest) has a more severe impact (Trickett et al., 2001; Wolfe, 2006). And repeated sexual abuse, like physical abuse, is associated with central nervous system damage (Cicchetti, 2007).

Sexually abused children frequently display precocious sexual knowledge and behavior. In adolescence, abused young people often become promiscuous, and as adults, they show increased arrest rates for sex crimes (mostly against children) and prostitution (Salter et al., 2003; Whipple, 2006). Furthermore, women who were sexually abused are likely to choose partners who abuse them and their children. As mothers, they often engage in irresponsible and coercive parenting, including child abuse and neglect (Pianta, Egeland, & Erickson, 1989). In these ways, the harmful impact of sexual abuse is transmitted to the next generation.

Prevention and Treatment

Treating child sexual abuse is difficult. The reactions of family members—anxiety about harm to the child, anger toward the abuser, and sometimes hostility toward the victim for telling—can increase children's distress. Because sexual abuse typically appears in the midst of other serious family problems, long-term therapy with children and parents is usually needed (Olafson & Boat, 2000). The best way to reduce the suffering of victims is to prevent sexual abuse from continuing. Today, courts are prosecuting abusers more vigorously and taking children's testimony more seriously (see Chapter 7).

Educational programs that teach children to recognize inappropriate sexual advances and whom to turn to for help reduce the risk of abuse (Finkelhor, 2009). Yet because of controversies over educating children about sexual abuse, few schools offer these interventions. New Zealand is the only country with a national, school-based prevention program targeting sexual abuse. In Keeping Ourselves Safe, children and adolescents learn that abusers are rarely strangers. Parent involvement ensures that home and school collaborate in teaching children self-protection skills. Evaluations reveal that virtually all New Zealand parents and children support the program and that it has helped many children avoid or report abuse (Sanders, 2006).

situations with high emotional arousal. And low income, low education (less than a high-school diploma), unemployment, alcohol and drug use, marital conflict, domestic violence, overcrowded living conditions, frequent moves, and extreme household disorganization are common in abusive homes (Wekerle et al., 2007; Wulczyn, 2009). These conditions increase the chances that parents will be too overwhelmed to meet basic child-rearing responsibilities or will vent their frustrations by lashing out at their children.

The Community The majority of abusive and neglectful parents are isolated from both formal and informal social supports. Because of their life histories, many have learned to mistrust and avoid others and are poorly skilled at establishing and maintaining positive relationships. Also, maltreating parents are more likely to live in unstable, crime-ridden neighborhoods with few links between family and community, such as parks, recreation centers, and religious institutions—living conditions that heighten parenting stress and, thus, the likelihood of physical abuse (Coulton et al., 2007; Guterman et al., 2009). These families lack "lifelines" to others and have no one to turn to for help during stressful times.

The Larger Culture Cultural values, laws, and customs profoundly affect the chances that child maltreatment will occur when parents feel overburdened. Societies that view violence as an appropriate way to solve problems set the stage for child abuse.

Although the United States has laws to protect children from maltreatment, widespread support exists for use of physical force with children, as we saw in Chapter 12. Many countries—including Austria, Croatia, Cyprus, Denmark, Finland, Germany, Israel, Latvia, Norway, Spain, Sweden, and Uruguay—have outlawed corporal punishment, a measure that dampens both physical discipline and abuse (Zolotor & Puzia, 2010). Furthermore, all industrialized nations except the United States and France now prohibit corporal punishment in schools (Center for Effective Discipline, 2005). The U.S. Supreme Court has twice upheld the right of school officials to use corporal punishment. Fortunately, 20 U.S. states have passed laws that ban it.

Consequences of Child Maltreatment

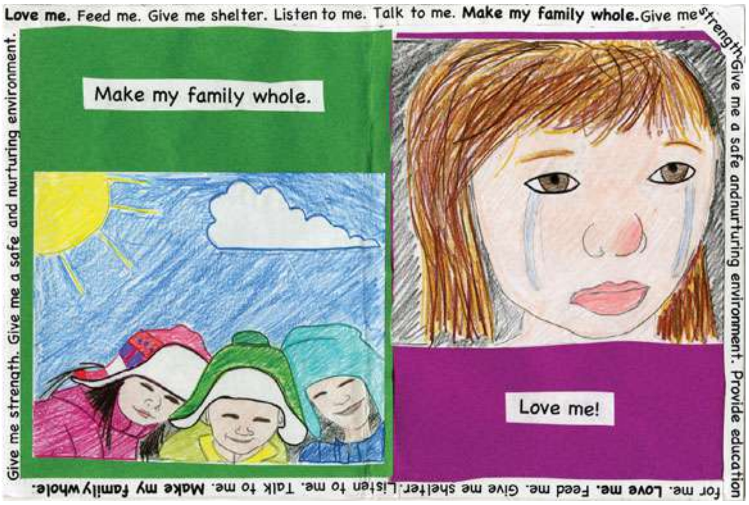
The family circumstances of maltreated children impair the development of attachment (see Chapter 10), emotional self-regulation, empathy and sympathy, self-concept, social skills, and academic motivation. Over time, these youngsters show serious adjustment problems, including school failure, severe depression, aggressive behavior, peer difficulties, substance abuse, and violent crime (Cicchetti & Toth, 2006; Sanchez & Pollak, 2009; Wolfe et al., 2001). Emotional and behavior problems often persist into adulthood (Kaplow & Widom, 2007).

How do these damaging consequences occur? Recall our discussion in Chapter 12 of hostile cycles of parent–child interaction. For abused children, these are especially severe. Also, a family characteristic strongly associated with child abuse is partner abuse (Gewirtz & Edleson, 2004; Kitzmann et al., 2003). Clearly, the home lives of abused children overflow with adult conduct that leads to profound distress, including emotional insecurity (see page 571), and to aggression as a way of solving problems.

Furthermore, demeaning parental messages, in which children are ridiculed, humiliated, rejected, or terrorized, result in low self-esteem, high anxiety, self-blame, depression, and efforts to escape from extreme psychological pain—at times severe enough to lead to attempted suicide in adolescence (Wolfe, 2005). At school, maltreated children present serious discipline problems. Their noncompliance, poor motivation, and cognitive immaturity interfere with academic achievement, further undermining their chances for life success (Wekerle & Wolfe, 2003).

Finally, repeated abuse is associated with central nervous system damage, including abnormal EEG brain-wave activity, fMRI-detected reduced size and impaired functioning of the cerebral cortex and corpus callosum, and atypical production of the stress hormone cortisol—initially too high but, after months of abuse, often too low. Over time, the massive trauma of persistent abuse seems to blunt children's normal physiological response to stress (Cicchetti, 2007; Teicher et al., 2004; Watts-English et al., 2006). These effects increase the chances that abused children's cognitive and emotional problems will endure.

Preventing Child Maltreatment



Love me. Feed me. Give me shelter. Listen to me. Talk to me. Make my family whole. Give me strength.
Give me a safe and nurturing environment. Provide education
for me. Love me. Feed me. Give me shelter. Listen to me. Talk to me. Make my family whole.
Give me strength. Give me a safe and nurturing environment.
Make my family whole.
Love me!

This poster by a sixth grader, expressing her wish for "a safe and nurturing environment," won an award from the Inter-Agency Council on Child Abuse and Neglect. (Courtesy ICAN Associates, Los Angeles County Inter-Agency Council on Child Abuse & Neglect, ican4kids.org.)

Because child maltreatment is embedded in families, communities, and society as a whole, efforts to prevent it must be directed at each of these levels. Many approaches have been suggested, from teaching high-risk parents effective child-rearing strategies to developing broad social programs aimed at improving economic conditions and community services.

We have seen that providing social supports to families is effective in easing parental stress. This approach sharply reduces child maltreatment as well (Azar & Wolfe, 1998). A trusting relationship with another person is the most important factor in preventing mothers with childhood histories of abuse from repeating the cycle with their own youngsters (Egeland, Jacobvitz, & Sroufe, 1988). Parents Anonymous, a U.S. organization with affiliate programs around the world, helps child-abusing parents learn constructive parenting practices, largely through social supports. Its local chapters offer self-help group meetings, daily phone calls, and regular home visits to relieve social isolation and teach responsible child-rearing skills.

Early intervention aimed at strengthening both child and parent competencies can improve parenting practices, thereby preventing child maltreatment (Howard & Brooks-Gunn, 2009). Healthy Families America, a program that began in Hawaii and has spread to 430 sites across the United States and Canada, identifies families at risk for maltreatment during pregnancy or at birth. Each receives three years of home visitation, in which a trained worker helps parents manage crises, encourages effective child rearing, and puts parents in touch with community services to meet their own and their children's needs (Healthy Families America, 2011). In an evaluation in which over 600 families were randomly assigned to either intervention or control groups, Healthy Families home visitation alone reduced only neglect, not abuse (Duggan et al., 2004). But adding a *cognitive component* dramatically increased its impact. When home visitors helped parents change negative appraisals of their children—by countering inaccurate interpretations (for example, that the baby is behaving with malicious intent), and by working on solving child-rearing problems—physical punishment and abuse dropped sharply by the end of one year of intervention (see Figure 14.7) (Bugental et al., 2002). Another home-visiting program shown to reduce child abuse and neglect is the Nurse–Family Partnership, discussed on page 220 in Chapter 5 (Olds et al., 2009).

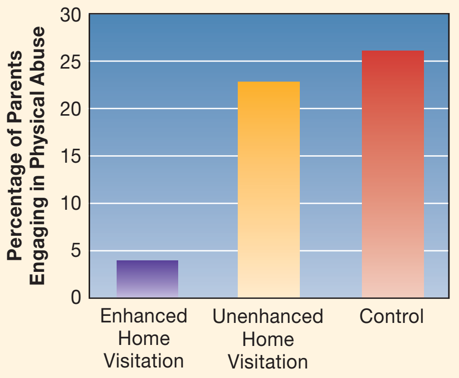


FIGURE 14.7 **Impact of a home visitation program with a cognitive component on preventing physical abuse of young children.** In an enhanced home visitation condition, home visitors not only provided social support, encouraged effective child rearing, and connected families with community resources but also helped at-risk parents change their negative appraisals of their babies and solve child-rearing problems. After one year of intervention, this cognitive component sharply reduced physical abuse of babies (hitting, shaking, beating, kicking, biting) compared with an unenhanced home visitation condition and a no-intervention control. (Adapted from Bugental et al., 2002.)

Still, many experts believe that child maltreatment cannot be eliminated as long as violence is widespread and harsh physical punishment is regarded as acceptable. In addition, combating poverty and its diverse correlates—family stress and disorganization, inadequate food and medical care, teenage parenthood, low-birth-weight babies, and parental hopelessness—would protect many children.

Although more cases reach the courts than in decades past, child maltreatment remains a crime that is difficult to prove. Usually, the only witnesses are the child victims or other loyal family members. And even when the evidence is strong, judges hesitate to impose the ultimate safeguard against further harm: permanently removing the child from the family. There are several reasons for their reluctance. First, in the United States, government intervention into family life is viewed as a last resort. Second, despite destructive family relationships, maltreated children and their parents usually are attached to one another. Most of the time, neither desires separation. Finally, the U.S. legal system tends to regard children as parental property rather than as human beings in their own right, and this also has stood in the way of court-ordered protection.

Even with intensive treatment, some adults persist in their abusive acts. An estimated 1,700 U.S. children, most of them infants and preschoolers, die from maltreatment each year (U.S. Department of Health and Human Services, 2010b). When parents are unlikely to change their behavior, the drastic step of separating parent from child and legally terminating parental rights is the only justifiable course of action.

Child maltreatment is a distressing and horrifying topic. When we consider how often it occurs in nations that claim to place a high value on the dignity and worth of the individual, it is even more appalling. But there is reason to be optimistic. Great strides have been made over the past several decades in understanding and preventing child maltreatment.

ASK YOURSELF

Review ■ Explain how personal and situational factors that contribute to child maltreatment illustrate the social systems perspective on family functioning.

Connect ■ After reviewing factors linked to adolescent parenthood (Chapter 5, pages 218–219), explain why it places children at risk for abuse and neglect.

Apply ■ Claire told her 6-year-old daughter to be careful never to talk to or take candy from strangers. Why is Claire's directive not adequate to protect her daughter from sexual abuse?

Reflect ■ Describe a challenging time for your family during your childhood. What aspects of the experience increased stress? What factors helped you and your parents cope with adversity?

SUMMARY

Origins and Functions of the Family (p. 568)

Discuss evolutionary origins of the family, and cite functions contemporary families perform for society.

- The family unit of our evolutionary ancestors enhanced survival by ensuring a relatively even balance of male hunters and female gatherers within a social group. Larger kin networks increased the chances of successful competition with other humans for resources and provided assistance with child rearing.
- Though contemporary families share some functions with other institutions, they retain primary responsibility for reproduction, socialization, and emotional support.

The Family as a Social System (p. 569)

Describe the social systems perspective on family functioning.

- Contemporary researchers view the family from a **social systems perspective**—as a complex set of interacting relationships influenced by the larger social context. Family members mutually influence one another, both directly and indirectly. Effective **coparenting** depends on cooperation between parents. Connections to the community, through both formal organizations and informal social networks, provide social support that promotes effective family interaction and children's development.

Socialization Within the Family (p. 573)

Discuss child-rearing styles, and explain how effective parents adapt child rearing to children's growing competence.

- Three features differentiate major **child-rearing styles:** (1) acceptance and involvement; (2) behavioral control; and (3) autonomy granting. The **authoritative child-rearing style** involves high acceptance and involvement, adaptive control techniques, and appropriate autonomy granting. It promotes cognitive, emotional, and social competence from early childhood into adolescence in children of diverse temperaments. Over time, the authoritative style creates a positive emotional context for parental influence as the relationship between parenting and children's attributes becomes increasingly bidirectional.
- The **authoritarian child-rearing style** is low in acceptance and involvement, high in coercive behavioral and **psychological control,** and low in autonomy granting. It is associated with anxious, withdrawn, dependent child behavior and with high rates of anger, defiance, and aggression. The **permissive child-rearing style** is high in acceptance, low in behavioral control, and lax in autonomy granting. Children reared permissively are typically impulsive, disobedient, rebellious, demanding, and dependent. The **uninvolved child-rearing style** combines low acceptance and involvement with little behavioral control and indifference to autonomy issues. At its extreme, it constitutes neglect, disrupting virtually all aspects of development.
- In middle childhood, effective parents engage in **coregulation,** exerting general oversight over children, who increasingly make their own decisions. During adolescence, mature **autonomy** is fostered by parenting that strikes a balance between connection and separation.

© RADIUS IMAGES/ALAMY

Describe socioeconomic and ethnic variations in child rearing, including the impact of affluence and poverty.

- Although the authoritative style predicts favorable development in children varying widely in SES and culture, SES and ethnic differences in parenting exist. Higher-SES parents are more verbal and stimulating, relying more on warmth and explanations; low-SES parents use more commands, criticism, and coercive discipline.

- The constant stressors linked to poverty result in less involved child rearing. Daily hassles, hostile family interactions, and depleted home learning environments negatively affect children's cognitive and emotional well-being.
- By adolescence, children of affluent parents often have academic, emotional, and substance abuse problems. Excessive achievement pressures and emotional isolation from parents underlie their difficulties.
- Chinese, Hispanic, Asian Pacific Island, and low-SES African-American parents tend to be controlling, which can be adaptive when combined with warmth. But excessive control impairs children's adjustment.
- Extended-family households are common among ethnic minorities and help protect children from the stress and disorganization of poverty.

Family Lifestyles and Transitions (p. 584)

Describe the influence of family size on child rearing, and explain how sibling relationships affect development.

- Contrary to a widespread assumption, larger family size does not reduce life chances or intelligence. Rather, the link between family size and children's IQ reflects the fact that mothers with low IQs tend to bear more children.
- Despite declining family size, most children grow up with at least one sibling. Because of their frequency and emotional intensity, sibling interactions are unique contexts for expanding social competence. Sibling rivalry tends to increase in middle childhood, when parental comparisons become more frequent. In adolescence, sibling relationships often become less intense as teenagers strive for autonomy, but attachment to siblings typically remains strong.
- Only children are as well-adjusted as children with siblings, and they are advantaged in self-esteem, academic achievement, and educational attainment.

How do children fare in adoptive, gay and lesbian, and never-married single-parent families?

- Adopted children tend to have more learning and emotional difficulties than other children, and by adolescence, their lives are often complicated by unresolved curiosity about their roots. By adulthood, however, most adoptees are well-adjusted.
- Gay and lesbian parents are as committed to and effective at child rearing as heterosexual parents. Their children are similar to other children in mental health, peer relations, gender-role behavior, and sexual orientation. During adolescence, more youths from homosexual families experiment with partners of both sexes.
- Never-married parenthood generally increases economic hardship for low-SES women. Children of never-married mothers who lack a father's warmth and involvement show less favorable cognitive development and engage in more antisocial behavior than children in low-SES, first-marriage families.

What factors influence children's adjustment to divorce and blended-family arrangements?

- Although all children experience painful emotional reactions during the period surrounding divorce, children with difficult temperaments and boys are at greater risk for adjustment problems. While children of divorce show improved functioning over time, divorce is linked to early sexual activity, adolescent parenthood, and long-term relationship difficulties.
- The overriding factor in positive adjustment following divorce is effective parenting. Positive father–child relationships foster favorable outcomes, as do caring extended family members, teachers, siblings, and friends. Divorce mediation and parent education programs can help promote parental cooperation.
- When divorced parents enter new relationships and form **blended**, or **reconstituted, families**, girls, older children, and children in father–stepmother families tend to have more adjustment problems. Stepparents who are warm and who move into their new roles gradually help children adjust.

How do maternal employment and life in dual-earner families affect children's development?

- When employed mothers enjoy their work and remain committed to parenting, their children show favorable adjustment. But when employment is stressful because of time demands or other reasons, children are at risk for ineffective parenting and adjustment difficulties.
- In dual-earner families, the father's willingness to share child-care responsibilities is linked to many positive child outcomes. Workplace supports, such as part-time employment, flexible schedules, and paid leave, help parents meet the demands of work and child rearing.

Discuss the influence of child-care quality on preschoolers' development and the impact of self-care on school-age children's adjustment.

- Preschoolers exposed to poor-quality care, especially for long hours, score lower in cognitive and social skills and higher in behavior problems.
- Key ingredients of high-quality child care include small group size, generous caregiver–child ratio, and caregivers' educational preparation and commitment to learning about and caring for children. High-quality care enhances cognitive, language, and social development, especially for low-SES children.

© JIM WEST/ALAMY

- Authoritative child rearing, parental monitoring, and regular after-school chores lead **self-care children** to be responsible and well-adjusted. Good "after-care" programs also aid school performance and emotional and social adjustment, with low-SES children showing special benefits.

Vulnerable Families: Child Maltreatment (p. 599)

Discuss the origins of child maltreatment, its consequences for development, and prevention strategies.

- Maltreating parents use ineffective discipline and hold negative biases toward their child. Unmanageable parental stress and social isolation increase the chances that abuse and neglect will occur. Societies that approve of the use of force and violence to solve problems promote child abuse.
- Maltreated children are impaired in development of attachment, emotional self-regulation, empathy and sympathy, self-concept, social skills, and academic motivation. They are also more likely to suffer central nervous system damage. Successful prevention of child maltreatment requires efforts at the family, community, and societal levels.

Stu and Pete became friends in their school's Connections program, which smoothes the transition to middle school by assigning small groups of sixth graders to the same classes and lunch hour, so they feel "connected" in their new, large-school environment. During an end-of-year discussion in health class, Ms. Stevens asked what their new-school experiences had been like.

"Well," Stu began, "at the beginning of the year, it wasn't easy. People were bouncing around, trying to find friends they felt comfortable with. I wasn't sure I was going to fit in. In the past few weeks, though, Pete and I just sort of clicked."

"Same with Katy and me," Jessamyn chimed in. "I used to have another group of friends in fifth grade, but I lost interest. I mean, when they got here, they were trying too hard to be popular."

"Can you explain that a little?" Ms. Stevens asked.

"Well, every time they talked to someone, they acted like a different person—kinda two-faced. It was annoying."

"How do you know someone's going to be a good friend?" asked Ms. Stevens.

"You've gotta have the same interests, and Stu and me, we've kinda got the same personality," replied Pete. "We both like computer stuff like playing games and instant messaging. Also, a friend has to be somebody who makes you feel good about yourself. I wouldn't be friends with someone who's always making me feel bad."

"Yeah," Katy agreed. "I know kids who'll say they're a friend but they're real nasty. They don't show any kindness or understanding. Mostly, everyone dislikes them."

Beyond the family, which contexts strongly influence children and adolescents? The answer is clear: peers, with whom they share countless play, classroom, and extracurricular activities; media—especially television, computers, cell phones, and the Internet, which consume large amounts of their free time; and school, which helps the family transmit culturally valued knowledge to the next generation.

In the first part of this chapter, we look closely at the development of peer sociability, friendship, peer acceptance, and peer groups, along with their profound significance for children's social competence and adjustment. Next we consider the impact of various media on cognitive and social development. Finally, we turn to the school—how class and school size, educational philosophy, teacher–student interaction, and grouping of students affect educational experiences and learning. We conclude with a look at schooling and achievement in international perspective, with special attention to how well American schools prepare young people for productive work lives. ■

Peer Relations

Are peer relations crucial for development, and how do they add to children's experiences with caring adults? In previous chapters, we saw that parent and peer relations complement one another. A secure attachment bond and authoritative parenting grant children the confidence, social-cognitive understandings, and social skills they need to

- Trace the development of peer sociability from infancy into adolescence, and discuss various influences on peer sociability.
- Describe developing concepts and characteristics of friendships in childhood and adolescence, as well as implications of friendship for psychological adjustment.
- Describe categories of peer acceptance, the relationship of social behavior to likability, and ways to help rejected children.
- Discuss peer group formation and dating relationships, including their consequences for development.
- What factors influence conformity to peer pressure in adolescence?

enter the world of peers and form gratifying peer relationships (see Chapters 10 and 14). Peer interaction, in turn, enables children to expand their social-cognitive knowledge and social skills (see Chapters 11, 12, and 13). And in circumstances where children face profound stressors, such as parental divorce, gratifying friendships with peers can stand in, to some extent, for a supportive parent–child relationship (see Chapter 14).

In sum, peers contribute greatly to development and serve as vital sources of support in threatening situations. But as our discussion will reveal once again, they do so more effectively when children have a history of warm, supportive ties to parents.

Development of Peer Sociability

In cultures where agemates have regular contact during the first year of life, peer sociability begins early, gradually evolving into the complex, well-coordinated exchanges of childhood and adolescence. Peer sociability is supported by and contributes greatly to cognitive, emotional, and social milestones discussed in previous chapters.

Infant and Toddler Beginnings

When pairs of infants are brought together in a laboratory, looking accompanied by touching is present at 3 to 4 months, peer-directed smiles and babbles by 6 months. These isolated social acts increase until, by the end of the first year, an occasional reciprocal exchange occurs in which babies grin, gesture, or otherwise imitate a playmate's behavior (Vandell & Mueller, 1995). Between 1 and 2 years, as toddlers appreciate that others have intentions, desires, and emotions distinct from their own, they increasingly view one another as playmates (Brownell & Kopp, 2007). As a result, coordinated interaction occurs more often, largely in the form of offering each other objects, sharing positive emotions, and mutual imitation involving jumping, chasing, or banging a toy (Vandell et al., 2006; Williams, Mastergeorge, & Ontai, 2010). These exchanges promote peer engagement and create joint understandings that aid verbal communication.

© DAVID YOUNG-WOLFF/ALAMY

Babies express peer sociability in touches, smiles, and babbles that gradually develop into coordinated interaction—mostly in the form of mutual imitation—during the second year.

Around age 2, toddlers use words to share meanings and establish play goals, as when they say, "Let's play chase," and, after the game gets going, "Hey, good running!" (Eckerman & Peterman, 2001). Reciprocal play and positive emotion are especially frequent in toddlers' interactions with familiar agemates, suggesting that they are building true peer relationships (Ross et al., 1992).

Though limited, peer sociability is present in the first two years and is promoted by the early caregiver–child bond. From interacting with sensitive adults, babies learn how to send and interpret emotional signals in their first peer associations (Trevarthen, 2003). Toddlers who have a warm parental relationship or who attend high-quality child care with a small group size and a generous caregiver–child ratio—features that promote warm, stimulating caregiving and gentle support for engaging with peers—display more positive and extended peer exchanges. These children, in turn, show more socially competent behavior as preschoolers (Deynoot-Schaub & Riksen-Walraven, 2006a, 2006b; Howes & Matheson, 1992; Williams, Mastergeorge, & Ontai, 2010).

The Preschool Years

As children become increasingly self-aware and better at communicating and at understanding others' thoughts and feelings, their skill at interacting with peers improves rapidly. Mildred Parten (1932), one of the first to study peer sociability among 2- to 5-year-olds, noticed a dramatic increase with age in joint, interactive play. She concluded that social development proceeds in a three-step sequence. It begins with **nonsocial activity**—unoccupied, onlooker behavior and solitary play. Then it shifts to **parallel play,** a limited form of social participation in which a child plays near other children with similar materials but does not try to influence their behavior. At the highest level are two forms of true social interaction. In **associative play,** children engage in separate activities but exchange toys and comment on one another's behavior. Finally, in **cooperative play,** a more advanced type of interaction, children orient toward a common goal, such as acting out a make-believe theme.

Longitudinal evidence indicates that these play forms emerge in the order Parten suggested but that later-appearing forms do not replace earlier ones in a developmental sequence (Rubin, Bukowski, & Parker, 2006). Rather, all types coexist during the preschool years. **TAKE A MOMENT...** Watch children move from one play type to another in a playgroup or preschool classroom, and you will see that they often transition from onlooker to parallel to cooperative play and back again (Robinson et al., 2003). Preschoolers seem to use parallel play as a way station—a respite from the high demands of complex social interaction and a crossroad to new activities. And although nonsocial activity declines with age, it is still the most frequent form among 3- to 4-year-olds. Even among kindergartners it continues to occupy about one-third of children's free-play time. Also, both solitary and parallel play remain fairly stable from 3 to 6 years, accounting for as much of the young child's play as highly social, cooperative interaction (Rubin, Fein, & Vandenberg, 1983).

© LAURA DWIGHT PHOTOGRAPHY

These 4-year-olds engage in parallel play, which seems to serve as a respite from the demands of complex social interaction and as a crossroad to new activities.

We now understand that it is the *type,* not the amount, of solitary and parallel play that changes during early childhood. In studies of preschoolers' play in Taiwan and the United States, researchers rated the *cognitive maturity* of nonsocial, parallel, and cooperative play by applying the categories shown in Table 15.1. Within each of Parten's play types, older children engaged in more cognitively mature behavior than younger children (Pan, 1994; Rubin, Watson, & Jambor, 1978).

LOOK and LISTEN

Observe several 3- to 5-year-olds during a free-play period in a preschool or child-care program. How much time does each child devote to nonsocial activity, parallel play, and socially interactive play? Do children seem to use parallel play as a way station between activities?

Often parents wonder whether a preschooler who spends large amounts of time playing alone is developing normally. But only *certain types* of nonsocial activity—aimless wandering, hovering near peers, and functional play involving immature, repetitive motor action—are cause for concern. Children who behave reticently, by watching peers without playing, are usually temperamentally inhibited—high in social fearfulness (Coplan et al., 2004; Rubin, Bukowski, & Parker, 2006; Rubin, Burgess, & Hastings, 2002). And children who engage in solitary, repetitive behavior (banging blocks, making a doll jump up and down) tend to be immature, impulsive youngsters who find it difficult to regulate anger and aggression (Coplan et al., 2001). In the classroom, both reticent and impulsive children experience peer ostracism, with boys at greater risk for rejection than girls (Coplan & Arbeau, 2008).

But other preschoolers with low rates of peer interaction are not socially anxious or impulsive. They simply prefer to play alone, and their solitary activities are positive and constructive. Teachers encourage such play by setting out art materials, books, puzzles, and building toys. Children who spend much time at these activities are usually well-adjusted youngsters who, when they do play with peers, show socially skilled behavior (Coplan & Armer, 2007). Still, a few preschoolers who engage in such age-appropriate solitary play—again, more often boys—are rebuffed by peers. Perhaps because quiet play is inconsistent with the "masculine" gender role, boys who engage in it are at risk for negative reactions from both parents and peers and, eventually, for adjustment problems (Coplan et al., 2001, 2004).

TABLE 15.1 **Developmental Sequence of Cognitive Play Categories**

PLAY CATEGORY	DESCRIPTION	EXAMPLES
Functional play	Simple, repetitive motor movements with or without objects; especially common during the first two years	Running around a room, rolling a car back and forth, kneading clay with no intent to make something
Constructive play	Creating or constructing something; especially common between 3 and 6 years	Making a house out of toy blocks, drawing a picture, putting together a puzzle
Make-believe play	Acting out everyday and imaginary roles; especially common between 2 and 6 years	Playing house, school, or police officer; acting out storybook or television characters
Games with rules	Understanding and following rules in play activities	Playing board games, cards, hopscotch, baseball

Source: Rubin, Fein, & Vandenberg, 1983.

As noted in Chapter 6, *sociodramatic play*—an advanced form of cooperative play—becomes especially common during the preschool years and supports cognitive, emotional, and social development (Göncü, Patt, & Kouba, 2004). In joint make-believe, preschoolers act out and respond to one another's pretend feelings. They also explore and gain control of fear-arousing experiences when they play doctor or pretend to search for monsters in a magical forest. As a result, they can better understand others' feelings and regulate their own

(Smith, 2003). Finally, to create and manage complex plots, preschoolers must resolve their disputes through negotiation and compromise. With age, preschoolers' disagreements center less on toys and other resources and more on differences of opinion—an indication of their expanding capacity to consider others' attitudes and ideas (Chen et al., 2001; Hay, Payne, & Chadwick, 2004).

Middle Childhood and Adolescence When formal schooling begins, children are exposed to agemates who vary in many ways, including achievement, ethnicity, religion, interests, and personality. Contact with a diversity of peers strengthens school-age children's awareness of a multiplicity of viewpoints (see Chapter 11). Peer communication, in turn, profits from improved perspective taking. Children of this age can better interpret others' emotions and intentions and take them into account in peer dialogues. They are also aware of the value of emotional display rules in facilitating social interaction (see Chapter 10) (Denham et al., 2004). And school-age children's ability to understand the complementary roles of several players in relation to a set of rules permits the transition to rule-oriented games (refer again to Table 15.1).

School-age children apply their emotional and social knowledge to peer communication. Recall from Chapter 12 that sharing, helping, and other prosocial acts increase in middle childhood. In addition, younger and older children differ in how they help agemates. Kindergartners move right in and give assistance, regardless of whether it is desired. In contrast, school-age children offer to help and wait for a peer to accept before behaving prosocially. In adolescence, agemates work on tasks more cooperatively—staying on task, freely exchanging ideas, asking for opinions, and acknowledging one another's contributions (Azmitia, 1996).

Another form of peer interaction emerges in the preschool years and peaks during middle childhood, when it accounts for 10 percent of free-play behavior. **TAKE A MOMENT...** While watching children at play in a city park or a schoolyard, notice how they occasionally wrestle, roll, hit, and run after one another, alternating roles while smiling and laughing. This friendly chasing and play-fighting is called **rough-and-tumble play.** Children in many cultures engage in it with peers whom they like especially well (Pellegrini, 2004). After a rough-and-tumble episode, they continue interacting rather than separating, as they do after an aggressive encounter.

© PHOTO AND CO/GETTY IMAGES/LIFESIZE

The good-natured quality of children's rough-and-tumble play distinguishes it from aggression. In our evolutionary past, rough-and-tumble may have been important for developing fighting skill and dominance relations.

Children's rough-and-tumble play resembles the social behavior of many other young mammals. It seems to originate in parents' physical play with babies, especially fathers' play with sons (see Chapter 10). And it is more common among boys, probably because prenatal exposure to androgens predisposes boys toward active play (see Chapter 13). Boys' rough-and-tumble largely consists of playful wrestling, restraining, and hitting, whereas girls tend to engage in running and chasing, with only brief physical contact (Boulton, 1996).

In our evolutionary past, rough-and-tumble play may have been important for the development of fighting skill (Power, 2000). It also may help children establish a **dominance hierarchy**—a stable ordering of group members that predicts who will win when conflict arises. Observations of arguments, threats, and physical attacks between children reveal a consistent lineup of winners and losers that becomes increasingly stable in middle childhood and adolescence, especially among boys. Once school-age children establish a dominance hierarchy, hostility is rare (Pellegrini & Smith, 1998; Roseth et al., 2007). Children seem to use play-fighting as a safe context to assess the strength of a peer before challenging that peer's dominance.

As adolescents reach physical maturity, individual differences in strength become apparent, and rough-and-tumble play declines. When it does occur, its meaning changes: Adolescent boys' rough-and-tumble is linked to aggression (Pellegrini, 2003). After becoming embroiled in a bout, players "cheat" and hurt their opponent. In explanation, boys often say that they are retaliating, apparently to reestablish dominance. And boy–girl rough-and-tumble, though infrequent, rises slightly at adolescence, perhaps serving as a means through which teenagers playfully initiate heterosexual interaction (Pellegrini, 2006, 2009).

Over middle childhood, children interact increasingly often with peers until, by mid-adolescence, they spend more time with peers than with any other social partners (Brown & Larson, 2009). Common interests, novel play activities, and opportunities to interact on an equal footing make peer interaction highly enjoyable. As adolescence draws to a close, most young people are proficient at many complex social behaviors.

Influences on Peer Sociability

Children first acquire skills for interacting with peers within the family. Parents influence children's peer sociability both *directly,* through attempts to influence children's peer relations, and *indirectly,* through their child-rearing practices and play behaviors (Ladd & Pettit, 2002; Rubin et al., 2005). Situational factors that adults can influence, such as the age mix of children, also make a difference, as do cultural values.

© LAURA DWIGHT PHOTOGRAPHY

A father gives his child a gentle lesson in getting along with others. Parents influence children's peer interaction skills by offering advice, guidance, and examples of how to behave.

Direct Parental Influences Outside preschool, child care, and kindergarten, young children depend on parents to help them establish rewarding peer associations. Preschoolers whose parents frequently arrange informal peer play activities tend to have larger peer networks and to be more socially skilled (Ladd, LeSieur, & Profilet, 1993). In providing play opportunities, parents show children how to initiate peer contacts and encourage them to be good "hosts" who consider their playmates' needs.

Parents also influence children's peer interaction skills by offering guidance on how to act toward others. Their skillful suggestions for managing conflict, discouraging teasing, and entering a play group are associated with preschoolers' social competence and peer acceptance (Mize & Pettit, 2010; Parke et al., 2004b). As children get older and acquire effective social skills, they need less parental advice. In middle childhood and adolescence, heavy provision of parental guidance is usually aimed at children with peer-relationship problems (McDowell & Parke, 2009; Mounts, 2011).

Recall from Chapter 14 that during middle childhood and adolescence, parental monitoring of their child's activities protects school-age children and adolescents from antisocial involvements. Young people's disclosure of information is vital for successful monitoring. The extent to which adolescents tell parents about their whereabouts and companions is an especially strong predictor of adjustment (Brown & Bakken, 2011; Stattin & Kerr, 2000). Such disclosure, however, depends on a history of consistent monitoring and a well-functioning parent–child relationship, which (as we will see) also promotes positive peer relations.

Indirect Parental Influences Many parenting behaviors not directly aimed at promoting peer sociability nevertheless influence it. For example, inductive discipline and authoritative parenting offer a firm foundation for competence in relating to agemates. In contrast, coercive behavioral control, including harsh physical punishment, and psychological control engender poor social skills and aggressive behavior (see Chapters 12 and 14).

Furthermore, secure attachments to parents are linked to more responsive, harmonious peer interactions, larger peer networks, and warmer, more supportive friendships throughout childhood and adolescence (Laible, 2007; Lucas-Thompson & Clarke-Stewart, 2007; Wood, Emmerson, & Cowan, 2004). The sensitive, emotionally expressive parental communication that contributes to attachment security may be responsible. In one study, researchers observed parent–child conversations and rated them for the strength of the mother–child bond, as indicated by exchanges of positive emotion and parental sensitivity to the child's statements and feelings. Kindergartners who were more emotionally "connected" to their mothers displayed more empathy and prosocial behavior toward their classmates. This empathic orientation, in turn, was linked to more positive peer ties (Clark & Ladd, 2000).

Parent–child play seems particularly effective for promoting peer interaction skills. During play, parents interact with their child on a "level playing field," much as peers do (Russell, Pettit, & Mize, 1998). Highly involved, emotionally positive, and cooperative play between parents and preschoolers is associated with more positive peer relations. And perhaps because parents play more with children of their own sex, mothers' play is more strongly linked to daughters' competence, fathers' play to sons' competence (Lindsey & Mize, 2000; Pettit et al., 1998).

Finally, the quality of parents' social networks is associated with children's social competence. In one study, parents who reported high-quality friendships had school-age children who interacted more favorably with friends. This relationship was stronger for girls, perhaps because girls spend more time near parents and have more opportunity to observe their parents' friends (Simpkins & Parke, 2001). Furthermore, overlap between parents' and adolescents' social networks—frequent contact among teenagers' friends, their parents, and their friends' parents—is related to better school achievement and low levels of antisocial behavior (Parke et al., 2004b). Under these conditions, other adults in parents' networks may promote parents' values and goals and monitor teenagers in their parents' absence.

Age Mix of Children

When observed in age-graded settings, such as child-care centers, schools, and summer camps, children typically interact with others close in age. Yet in cultures where children are not segregated by age for schooling and recreation, cross-age interaction is common.

The theories of Piaget and Vygotsky, discussed in Chapter 6, suggest different benefits from same- versus mixed-age interaction. Piaget emphasized experiences with children equal in status who challenge one another's viewpoints, thereby promoting cognitive, social, and moral development. In contrast, Vygotsky believed that children profit from interacting with older, more capable peers, who model and encourage more advanced skills.

Among preschoolers, younger children's play is more cognitively and socially mature in mixed-age classrooms than in single-age classrooms. Furthermore, as early as age 3 or 4, children can modify their behavior to fit the needs of a less advanced child, simplifying their communication and assuming more responsibility for a joint activity (Brody, Graziano, & Musser, 1983; Howes & Farver, 1987). Nevertheless, the oldest school-age children in mixed-age settings prefer same-age companions, perhaps because they have more compatible interests and experience more cooperative interaction. Younger children's interaction with same-age partners is also more intense and harmonious, but they often turn to older peers because of their superior knowledge and exciting play ideas.

Children clearly profit from both same-age and mixed-age relationships. From interacting with equals, they learn to cooperate and resolve conflicts, and they develop vital moral understandings of reciprocity and justice (see Chapters 11 and 12). In mixed-age settings, younger children acquire new competencies from their older companions. And when more mature youngsters help their less mature counterparts, they practice nurturance, guidance, and other prosocial behaviors.

Village children in India play a "circle tapping" game requiring high levels of cooperation. The child in the center recites a poem, the alphabet, or numbers, then circles the others, saying, "Whomever I tap, it will be their turn." The tapped child recites next.

Cultural Values

Peer sociability in collectivist societies, which stress group harmony, takes different forms than in individualistic cultures (Chen & French, 2008). For example, children in India generally play in large groups, which requires high levels of cooperation. Much of their behavior is imitative, occurs in unison, and involves close physical contact. In a game called Bhatto Bhatto, children act out a script about a trip to the market, touching one another's elbows and hands as they pretend to cut and share a tasty vegetable (Roopnarine et al., 1994).

As another example, Chinese preschoolers—unlike American preschoolers, who tend to reject reticent classmates—are typically willing to include a quiet, reserved child in play (Chen et al., 2006). In Chapter 10, we saw that until recently, collectivist values, which discourage self-assertion, led to positive evaluations of shyness in China (see page 427). Apparently, this benevolent attitude is still evident in the play behaviors of young Chinese children.

Cultural beliefs about the importance of play also affect early peer associations. Caregivers who view play as mere entertainment are less likely to provide props or to encourage pretend than those who value its cognitive and social benefits (Farver & Wimbarti, 1995a, 1995b). Preschool children of Korean-American parents, who emphasize task persistence as crucial for learning, spend less time than Caucasian-American children in joint make-believe and more time unoccupied and in parallel play (Farver, Kim, & Lee, 1995).

Return to the description of children's daily lives in a Mayan village culture on page 273 in Chapter 6. Mayan parents do not promote children's play—yet Mayan children are socially competent (Gaskins, 2000). Perhaps Western-style sociodramatic play, with its elaborate materials and wide-ranging themes, is particularly important for social development in societies where the worlds of adults and children are distinct than in village cultures where children participate in adult activities from an early age. In support of this view, observations of 2- to 6-year-olds in a Senagalese fishing village revealed that make-believe with peers was just as prevalent as in a comparison group of U.S. middle-SES agemates (Bloch, 1989). Because sea fishing is too risky an activity for young children, the Senegalese preschoolers spent much time in their homes and yards apart from working adults. Their families also had sufficient resources to provide them with a rich array of play materials that fostered pretending.

In all societies, peer contact rises in adolescence, a trend that is strongest in industrialized nations, where young people spend most of each weekday with agemates in school. Teenagers also spend much out-of-class time together, more in some cultures than in others. For example, U.S. young people have about 50 hours of free time per week, Europeans about 45 hours, and East Asians about 33 hours (Larson, 2001). A shorter school year and less demanding academic standards, which lead American youths to devote much less time to schoolwork, account for this difference (see Figure 15.1).

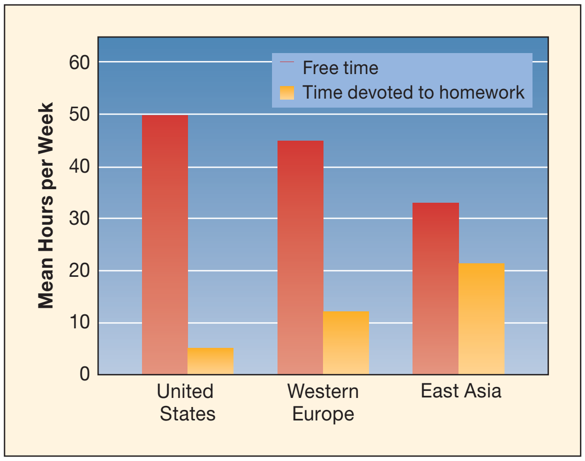

FIGURE 15.1 Weekly free time and time devoted to homework by adolescents in the United States, Europe, and East Asia. Figures are averages of those reported in many studies. American teenagers have more free time available to spend with peers than their European and, especially, Asian counterparts, largely because American adolescents spend far less time doing homework. (Adapted from Larson, 2001.)

ASK YOURSELF

Review ■ Among children who spend much time playing alone, what factors distinguish those who are likely to have adjustment difficulties from those who are well-adjusted and socially skilled?

Connect ■ What aspects of parent–child interaction probably account for the relationship between attachment security and children's peer sociability? (*Hint:* See Chapter 10, pages 434 and 437.)

Apply ■ Three-year-old Ben lives in the country, with no other preschoolers nearby. His parents wonder whether it is worth driving Ben into town once a week to participate in a peer play group. What advice would you give Ben's parents, and why?

Reflect ■ What did your parents do, directly and indirectly, that might have influenced your peer relationships in childhood and adolescence?

Friendship

Children have encounters and relationships with many peers, but they prefer some over others. Beginning in early childhood, they form **friendships**—close relationships involving companionship in which each partner wants to be with the other. Observations of 1- and 2-year-olds reveal that they initiate play, exchange expressions of positive emotion, and engage in more complex interactions with selected, familiar peers (Howes, 2009). These early mutual relationships may lay the groundwork for deeper, more meaningful friendships in childhood and adolescence.

To study friendship, researchers ask the child or a knowledgeable adult to name friends and then check whether nominated friends return the choice. They also observe friendship interactions, comparing them with other peer relationships. And they interview children about what friendship means. Findings reveal that with age, children's ideas about friendship change, as do certain features of friendships (Hartup, 2006). From the preschool years on, friendship contributes uniquely to children's emotional and social development.

Thinking About Friendship **TAKE A MOMENT...** Jot down a description of what *friendship* means to you. You probably pictured a consensual relationship involving companionship, sharing, understanding each other's thoughts and feelings, and caring for and comforting each other in times of need. In addition, mature friendships endure over time and survive occasional conflicts. But to a child, friendship begins far more concretely, as pleasurable activity. With age, friendship evolves into a relationship based on mutual consideration and emotional satisfaction (Hartup & Abecassis, 2004). Children's changing ideas about friendship follow a three-stage sequence, confirmed by both longitudinal and cross-sectional research:

1. **Friendship as a Handy Playmate (About 4 to 7 Years)** Preschoolers understand something about the uniqueness of friendship. They say that a friend is someone "who likes you," with whom you spend a lot of time playing, and with whom you share toys. But friendship does not yet have a long-term, enduring quality. Children at this stage say that a friendship can dissolve when one partner refuses to share, hits, or is not available to play. "Mark's my best friend," one 5-year-old would declare on days when the boys got along well (Damon, 1988; Hartup, 2006). But when a dispute arose, he would reverse himself: "Mark, you're not my friend!"

© GEORGE DISARIO/CORBIS

During middle childhood, concepts of friendship become more psychologically based. These boys share an interest in cooking, but they want to spend time together because they like each other's personal qualities.

2. **Friendship as Mutual Trust and Assistance (About 8 to 10 Years)** In middle childhood, friendship becomes more complex and psychologically based. Consider the following 8-year-old's ideas:

   > *Why is Shelly your best friend?* Because she helps me when I'm sad, and she shares. . . . *What makes Shelly so special?* I've known her longer, I sit next to her and got to know her better. . . . *How come you like Shelly better than anyone else?* She's done the most for me. She never disagrees, she never eats in front of me, she never walks away when I'm crying, and she helps me on my homework. . . . *How do you get someone to like you?* . . . If you're nice to [your friends], they'll be nice to you. (Damon, 1988, pp. 80–81)

   As these responses show, friendship has become a mutually agreed-on relationship in which children like each other's personal qualities and respond to each other's needs and desires. And once a friendship forms, *trust* becomes its defining feature. School-age children state that a good friendship is based on acts of kindness signifying that each person can be counted on to support the other (Hartup & Abecassis, 2004). Consequently, older children regard violations of trust, such as not helping a friend who needs help, breaking promises, and gossiping behind a friend's back, as serious breaches of friendship—as Katy did in the chapter introduction. And rifts cannot be patched up simply by playing nicely after a conflict, as preschoolers and young school-age children do. Instead, apologies and explanations are necessary.

3. **Friendship as Intimacy, Mutual Understanding, and Loyalty (11 to 15 Years and Older)** When asked about the meaning of friendship, teenagers stress three characteristics. The most important is *intimacy,* or psychological closeness, which is supported by *mutual understanding* of each other's values, beliefs, and feelings. In addition, more than younger children, teenagers want their friends to be *loyal*—to stick up for them and not to leave them for somebody else (Collins & Madsen, 2006).

   As friendship takes on these deeper features, adolescents regard it as formed over time by "getting to know someone." In addition, they view friends as important in relieving psychological distress, such as loneliness, sadness, and fear. Because true mutual understanding implies forgiveness, only an extreme falling out can terminate a friendship. Here is how one teenager described his best friendship:

   > Well, you need someone you can tell anything to, all kinds of things that you don't want to spread around. That's why you're someone's friend. *Is that why Jimmy is your friend? Because he can keep a secret?* Yes, and we like the same kinds of things. We speak the same language. My mother says we're two peas in a pod. . . . *Do you ever get mad at Jimmy?* Not really. *What if he did something that got you really mad?* He'd still be my best friend. I'd tell him what he did wrong and maybe he'd understand. I could be wrong too, it depends. (Damon, 1977, p. 163)

LOOK and LISTEN

Ask an 8- to 11-year-old to tell you what he or she looks for in a best friend. Is trust centrally important? Does the child mention personality traits, just as school-age children do in describing themselves (see Chapter 11, page 458).

Characteristics of Friendships

Changes in children's thinking about friendships are linked to characteristics of their real friendships. Let's look closely at friendship stability, interaction, and resemblance.

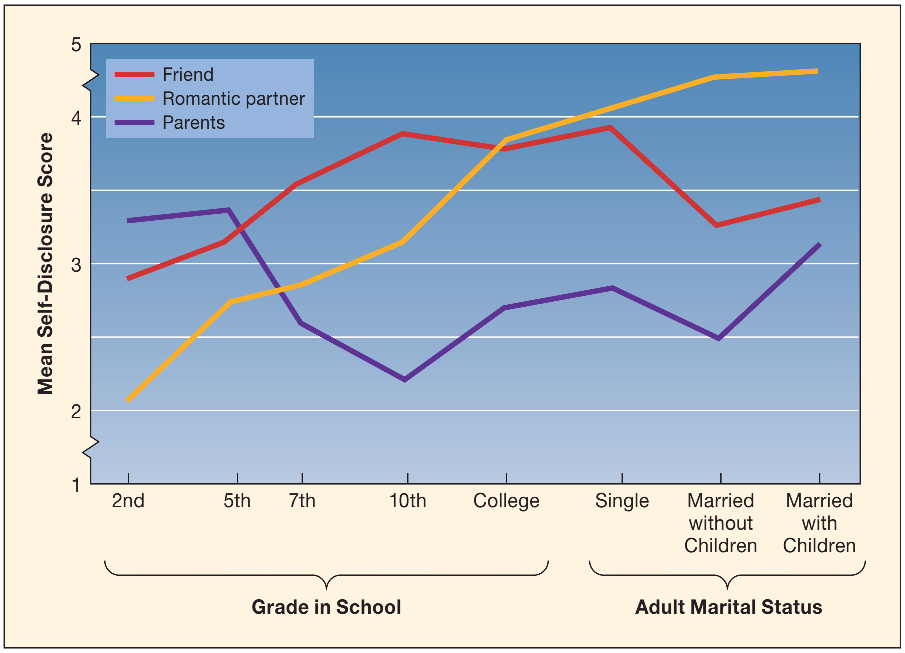

FIGURE 15.2 **Age changes in reported self-disclosure to parents and peers, based on data from several studies.** Self-disclosure to friends increases steadily during adolescence, reflecting intimacy as a major basis of friendship. Self-disclosure to romantic partners also rises, but it does not surpass intimacy with friends until the college years. Self-disclosure to parents declines in early adolescence, a time of mild parent–child conflict. As family relationships readjust to the young person's increasing autonomy, self-disclosure to parents rises. (From D. Buhrmester, 1996, "Need Fulfillment, Interpersonal Competence, and the Developmental Contexts of Early Adolescent Friendship," in W. M. Bukowski, A. F. Newcomb, & W. W. Hartup, Eds., *The Company They Keep: Friendship in Childhood and Adolescence,* New York: Cambridge University Press, p. 168. Reprinted with permission of Cambridge University Press.)

Friendship Selectivity and Stability. As mutual trust and loyalty increase in importance, school-age children's friendships become more selective. Preschoolers say they have lots of friends—sometimes, everyone in their class! But by age 8 or 9, children name only a handful of good friends. As teenagers focus on friendship quality, this narrowing continues. Number of best friends declines from four to six in early adolescence to only one or two in early adulthood (Hartup & Stevens, 1999).

Friendships are remarkably stable at all ages, but for younger children, stability is largely a function of the constancy of social environments, such as school and neighborhood. Context continues to be influential at older ages, with friendships spanning several situations—such as school, religious institution, and children of parents' friends—more likely to persist (Troutman & Fletcher, 2010). At the same time, stability increases with age as friendships become psychologically based and, therefore, higher in such positive features as intimacy, self-disclosure, support, and prosocial behavior. From fourth grade through high school, about 50 to 70 percent endure over the course of a school year, and some for several years, although they often undergo temporary shifts in the strength of each partner's commitment (Berndt, 2004; Degirmencioglu et al., 1998). In middle or junior high school, varying rates of pubertal development, encounters with new peers, and romantic interests often lead to a temporary period of greater change in choice of friends (Poulin & Chan, 2010).

Interaction Between Friends. At all ages, friends have special ways of interacting. Preschoolers, for example, give twice as much reinforcement—greetings, praise, and compliance—to children they identify as friends, and they also receive more from them. Friends are more emotionally expressive, talking, laughing, and looking at one another more often than nonfriends do (Hartup, 1996, 2006; Vaughn et al., 2001). Spontaneity, intimacy, and sensitivity characterize rewarding friendships very early, although children are not able to express these ideas until much later.

A more mature understanding of friendship seems to spark greater prosocial behavior between friends. When working on a task together, school-age friends help, share, refer to each other's comments, and spend more time focused than preschool friends do (Hartup, 1996; Newcomb & Bagwell, 1995). Cooperation, generosity, mutual affirmation, and self-disclosure (see Figure 15.2) continue to rise into adolescence—trends that may reflect greater effort and skill at preserving the relationship and increased sensitivity to a friend's needs and desires (De Goede, Branje, & Meeus, 2009; Phillipsen, 1999). Adolescents also are less possessive of their friends than they were in childhood (Parker et al., 2005). Desiring a certain degree of autonomy for themselves, they recognize that friends need this, too.

Friends not only behave more prosocially but also disagree and compete with each other more than nonfriends. Because children regard friendship as based on equality, they seem especially concerned about losing a contest to a friend. Also, when children hold differing opinions, friends are more likely to voice them. At the same time, school-age and adolescent friends use negotiation to resolve conflicts more often than nonfriends do. Friends seem to realize that close relationships can survive disagreements if both parties are secure in their liking for each other (Fonzi et al., 1997; Hartup, 2006; Rose & Asher, 1999). Clearly, friendship provides an important context in which children learn to tolerate criticism and resolve disputes.

The impact of friendships on children's development depends on the nature of those friends. Children who bring kindness and compassion to their friendships strengthen one another's prosocial tendencies and form more lasting ties (Vitaro, Boivin, & Bukowski, 2009). But when aggressive children make friends, the relationship is often riddled with hostile interaction and is at risk for breakup, especially when just one member of the pair is aggressive (Ellis & Zarbatany, 2007). Aggressive girls' friendships are high in self-disclosure but full of relational hostility, including jealousy, conflict, and betrayal—techniques used to manipulate associations with others. Aggressive boys' friendships involve frequent expressions of anger, coercive statements, physical attacks, and enticements to rule-breaking behavior, as well as relational aggression (Bagwell & Coie, 2004; Crick & Nelson, 2002; Dishion, Andrews, & Crosby, 1995). These findings indicate that the social problems of aggressive children operate within their closest peer ties.

Resemblance Between Friends. The value adolescents attach to feeling "in sync" with their friends suggests that friends will become increasingly similar in attitudes and values with age. Actually, the attributes on which friends are most alike throughout childhood and adolescence are age, sex, ethnicity, and SES. But from middle childhood on, friends also resemble one another in personality (sociability, inattention/hyperactivity, aggression, depression), popularity, academic achievement, prosocial behavior, and judgments (including biased perceptions) of other people (Hartup, 2006; Mariano & Harton, 2005). And in adolescence, friends tend to be alike in identity status, educational aspirations, political beliefs, and willingness to try drugs and engage in lawbreaking acts. Over time, they become more similar in these ways (Berndt & Murphy, 2002; Selfhout, Branje, & Meeus, 2008).

Children and adolescents probably choose companions like themselves in age, sex, and ethnicity to increase the supportiveness of friendship. In-group favoritism and out-group prejudice may also influence these choices (see Chapters 11 and 13). How do children identify peers who are similar to themselves in other ways? According to some researchers, they go on "shopping expeditions" in their social networks, trying out relationships and sustaining those that "feel right" (Hartup & Abecassis, 2004). As friends spend more time together, they socialize one another, becoming increasingly alike in attitudes, values, school grades, and social behavior (Berndt & Keefe, 1995).

Nevertheless, as young people enter a wider range of school and community settings, they choose some friends who differ from themselves. For a time, young teenagers sacrifice similarity in favor of admiration for superficial features—whether a potential friend is popular, physically attractive, or athletically skilled. And early adolescents of both sexes are attracted to high-status, aggressive boys as friends, a trend that contributes to a rise in antisocial behavior and, for girls, can lead to negative experiences in their first dating relationships (Bukowski, Sippola, & Newcomb, 2000). In other instances, a friend's favorable traits are influential. In one study, low-achieving 9- to 11-year-olds who befriended a high-achieving classmate declined in academic self-esteem (because of social comparison) but nevertheless improved in academic performance (Altermatt & Pomerantz, 2005).

The task of forging a personal identity may also lead adolescents to seek friends with differing attitudes and values, as a means of exploring new perspectives within the security of a compatible relationship. Furthermore, teenagers often judge commonality in certain attributes as more important than in others. For example, compared with Caucasian-American friends, African-American and Hispanic friends place greater emphasis on shared ethnicity and less on similarity in academic achievement (Azmitia, Ittel, & Brenk, 2006; Hamm, 2000). Nevertheless, Hispanic frequently view higher-achieving friends as a source of pride (Azmitia & Cooper, 2001). Such friends play key roles in spurring improved school performance and higher educational aspirations.

Finally, children and adolescents are more likely to form friendships with agemates of other ethnicities when they attend ethnically diverse schools and live in integrated neighborhoods (Quillian & Campbell, 2003).

© ANGELA HAMPTON PICTURE LIBRARY/ALAMY

Teenagers typically choose friends whose attitudes and values resemble their own. Early adolescents are also attracted to high-status aggressive boys—a trend that contributes to a rise in antisocial behavior.

As young people form comfortable, lasting close relationships, they come to view ethnically different peers as individuals instead of through the lens of stereotypes (see Chapter 11).

In adolescence, intimacy and loyalty become defining features of friendship. Compared to boys, girls place a higher value on emotional closeness, engaging in more self-disclosure and mutually supportive statements with friends.

Sex Differences in Friendships In middle childhood, children start to report a consistent sex difference in friendships: Emotional closeness is more common between girls than between boys (Markovits, Benenson, & Dolenszky, 2001). Girls, who are more exclusive in their friendships, frequently get together to "just talk," and their exchanges contain more self-disclosure (sharing of innermost thoughts and feelings) and mutually supportive statements. In contrast, boys more often gather for an activity—usually sports or other competitive games. Boys' discussions usually focus on recognition and mastery issues, such as achievements in sports and school, and involve more competition and conflict (Brendgen et al., 2001; Rubin, Bukowski, & Parker, 2006).

Because of gender-role expectations, girls' friendships typically focus on communal concerns, boys' on achievement and status. Boys do form close friendship ties, but the quality of their friendships is more variable. Gender identity plays a role: Androgynous boys are as likely as girls to form intimate same-sex ties, whereas highly "masculine" boys are less likely to do so (Jones & Dembo, 1989).

Friendship closeness has costs as well as benefits. When friends focus on their deeper thoughts and feelings, they tend to *coruminate,* or repeatedly mull over problems and negative emotions. Corumination, while contributing to high friendship quality, also triggers anxiety and depression—symptoms more common among girls than among boys (Hankin, Stone, & Wright, 2010; Rose, Carlson, & Waller, 2007). And when conflict arises between intimate friends, more potential exists for one party to harm the other through relational aggression—for example, by divulging sensitive personal information to outsiders.

Partly for this reason, girls' closest same-sex friendships tend to be of shorter duration than boys' (Benenson & Christakos, 2003). Also, whereas boys often resolve conflicts by minimizing their importance ("It's no big deal"), this strategy tends to result in friendship break-up among girls (Bowker, 2004). When friendships are emotionally intense, minimizing rather than being "up front" about tensions in the relationship may restore superficial harmony while the underlying discontent lingers, making the friendship less stable.

In early adolescence, young people who are either very popular or very unpopular are more likely to have other-sex friends. Teenagers who are not accepted by their own sex sometimes look to the other sex for friendships. Girls have more other-sex friends than boys, a difference that widens with age as teenage girls form friendships with boys who are somewhat older (Poulin & Pedersen, 2007). Among boys without same-sex friends, having an other-sex friend is associated with feelings of competence. But among girls who lack same-sex friends, other-sex friendships are linked to less positive well-being (Bukowski, Sippola, & Hoza, 1999). Perhaps these girls are especially likely to befriend boys with negative traits, such as aggression.

Friendship and Adjustment Warm childhood and adolescent friendships that are high in trust, intimate sharing, and support contribute to many aspects of psychological health and competence into early adulthood (Bukowski, 2001; Waldrip, 2008), for several reasons:

- *Close friendships provide opportunities to explore the self and develop a deep understanding of another.* Through open, honest communication, friends become sensitive to each other's strengths and weaknesses, needs and desires—a process that supports the development of self-concept, perspective taking, and identity.
- *Close friendships provide a foundation for future intimate relationships.* Look again at Figure 15.2, and you will see that self-disclosure to friends precedes disclosure to romantic partners. Conversations with teenage friends about sexuality and romance, along with the intimacy of friendship itself, may help adolescents establish and work out problems in romantic partnerships (Connolly & Goldberg, 1999; Sullivan, 1953).

- *Close friendships help young people deal with the stresses of everyday life.* By enhancing sensitivity to and concern for another, supportive, prosocial friendships promote empathy, sympathy, and prosocial behavior. As a result, they contribute to involvement in constructive youth activities, avoidance of antisocial acts, and psychological well-being (Lansford et al., 2003; Wentzel, Barry, & Caldwell, 2004). A rewarding friendship helps protect shy children from developing emotional and behavior problems (Laursen et al., 2007). And adolescents experiencing family stress who have close friends show as high a level of well-being as children from better-functioning families (Gauze et al., 1996).
- *Close friendships can improve attitudes toward and involvement in school.* Close friendships promote good school adjustment, academically and socially, in both middle- and low-SES students (Berndt & Murphy, 2002; Wentzel, Barry, & Caldwell, 2004). Children and adolescents who enjoy interacting with friends at school may begin to view all aspects of school life more positively.

Some friendships, however, interfere with well-being. Beginning in the preschool years, the conflict-ridden interactions that occur between physically, verbally, and relationally aggressive friends are associated with poor adjustment (Sebanc, 2003). Longitudinal research reveals that children with aggressive friends increase in antisocial behavior over time (Snyder et al., 2005; Vitaro, Pedersen, & Brendgen, 2007).

Finally, children who have no friends usually have undesirable personalities: They may be easily angered, shy and anxious, or self-centered (less caring and honest) (Bowker et al., 2006; Laursen et al., 2007). Without supportive friendship as a context for acquiring more adaptive social behaviors, the maladaptive behaviors of these children tend to persist.

ASK YOURSELF

Review ■ Describe unique qualities of interaction between close friends, and explain how they contribute to development.

Review ■ Why are aggressive children's friendships likely to magnify their antisocial behavior?

Connect ■ Cite similarities in development of self-concept, described in Chapter 11 (pages 456, 458), and ideas about friendship. Explain how the discussion among Stu, Pete, Jessamyn, and Katy in the introduction to this chapter reflects friendship expectations that typically emerge at adolescence.

Apply ■ Ralph, a high school junior of Irish Catholic background, befriended Jonathan, a Chinese-American of Buddhist faith. Both boys are from middle-SES homes and are good students. Why might Ralph seek out a friend both similar to and different from himself?

Peer Acceptance

Peer acceptance refers to likability—the extent to which a child is viewed by a group of agemates, such as classmates, as a worthy social partner. Unlike friendship, peer acceptance is not a mutual relationship but a one-sided perspective, involving the group's view of an individual. Nevertheless, certain social skills that contribute to friendship also enhance peer acceptance. Better-accepted children tend to have more friends and more positive relationships with them (Lansford et al., 2006b; Pedersen et al., 2007). Like friendship, peer acceptance contributes uniquely to children's adjustment.

To assess peer acceptance, researchers usually use self-reports that measure *social preferences*—for example, asking children and adolescents to identify classmates whom they "like very much" or "like very little" (Hymel et al., 2004). Another approach assesses *social prominence*—young people's judgments of the peers most of their classmates admire. Only moderate correspondence exists between the classmates school-age children and adolescents identify as prominent (looked up to by many others) and those they say they personally prefer (Prinstein & Cillessen, 2003).

Children's self-reports yield four general categories of peer acceptance:

- **Popular children,** who get many positive votes (are well-liked)
- **Rejected children,** who get many negative votes (are disliked)

- **Controversial children,** who receive many votes, both positive and negative (are both liked and disliked)
- **Neglected children,** who are seldom mentioned, either positively or negatively

About two-thirds of students in a typical elementary school classroom fit one of these categories (Coie, Dodge, & Coppotelli, 1982). The remaining one-third, who do not receive extreme scores, are *average* in peer acceptance.

Peer acceptance is a powerful predictor of current and later psychological adjustment. Rejected children, especially, are anxious, unhappy, disruptive, poorly achieving children with low self-esteem. Both teachers and parents view them as having a wide range of emotional and social problems. Peer rejection in middle childhood is also strongly associated with poor school performance, absenteeism, dropping out, substance use, depression, antisocial behavior, and delinquency in adolescence and with criminality in early adulthood (Ladd, 2005; Laird et al., 2001; Parker et al., 1995; Rubin, Bukowski, & Parker, 2006).

However, prior influences—children's characteristics combined with parenting practices—may largely explain the link between peer acceptance and psychological adjustment. School-age children with peer-relationship problems are more likely to have preexisting, weak emotional self-regulation skills and to have experienced family stress due to low income, insensitive child rearing, and coercive discipline (Cowan & Cowan, 2004; Trentacosta & Shaw, 2009). Nevertheless, as we will see, rejected children evoke reactions from peers that contribute to their unfavorable development. Peer rejection, in turn, adds to the risk of maladjustment, beyond rejected children's maladaptive behavioral styles (Sturaro et al., 2011).

Determinants of Peer Acceptance

Why is one child liked while another is rejected? A wealth of research reveals that social behavior plays a powerful role.

Popular Children. Although many popular children are kind and considerate, others are admired for their socially sophisticated yet belligerent behavior. Two subtypes of popular children exist.

Most are **popular-prosocial children,** who combine academic and social competence. They perform well in school, communicate with peers in friendly and cooperative ways, and solve social problems constructively (Cillessen & Bellmore, 2004; Newcomb, Bukowski, & Pattee, 1993).

A smaller subtype, **popular-antisocial children,** which emerges in late childhood and early adolescence, includes "tough" boys—athletically skilled but poor students who cause trouble and defy adult authority—and relationally aggressive boys and girls who enhance their own status by ignoring, excluding, and spreading rumors about other children (Rodkin et al., 2000; Rose, Swenson, & Waller, 2004; Vaillancourt & Hymel, 2006). Despite their aggressiveness, peers often view these youths as "cool," perhaps because of their athletic abilities and sophisticated but devious social skills.

Although peer admiration gives popular-antisocial children some protection against lasting adjustment difficulties, their antisocial acts require intervention (Prinstein & La Greca, 2004; Rodkin et al., 2006). With age, peers like these high-status, aggressive youths less and less, a trend that is stronger for relationally aggressive girls. The more socially prominent and controlling these girls become, the more they engage in relational aggression (Cillessen & Mayeux, 2004). Eventually peers may condemn their nasty tactics and reject them.

Rejected Children. Rejected children display a wide range of negative social behaviors. But as with popular children, not all of these disliked children look the same.

Rejected-aggressive children, the largest subtype, show high rates of conflict, physical and relational aggression, and hyperactive, inattentive, and impulsive behavior.

They are usually deficient perspective takers, misinterpreting the innocent behaviors of peers as hostile, blaming others for their social difficulties, and acting on their angry feelings (Crick, Casas, & Nelson, 2002; Hoza et al., 2005; Rubin, Bukowski, & Parker, 2006). Compared with popular-aggressive children, rejected-aggressive children are more extremely antagonistic (Prinstein & Cillessen, 2003). Rather than using aggression skillfully to attain status, rejected-aggressive children display blatantly hostile, acting-out behavior, which triggers scorn and avoidance in their peers.

In contrast, **rejected-withdrawn children** are passive and socially awkward. These timid children are overwhelmed by social anxiety, hold negative expectations for treatment by peers, and fear being scorned and attacked. Like their aggressive counterparts, they typically feel like retaliating rather than compromising in peer conflicts, although they less often act on those feelings (Hart et al., 2000; Rubin, Bowker, & Gazelle, 2010; Troop-Gordon & Asher, 2005).

Rejected children are excluded by peers as early as kindergarten. Rejection, in turn, further impairs these children's biased social information processing, heightening their hostility (Lansford et al., 2010). Soon their classroom participation declines, their feelings of loneliness and depression rise, their academic achievement falters, and they want to avoid school (Buhs, Ladd, & Herald-Brown, 2010; Gooren et al., 2011). Most have few friends, and their closest friendship bonds tend to be low in mutual support and effective conflict resolution (Rubin, Bukowski, & Parker, 2006). Some have no friends—a circumstance linked to low self-esteem, mistrust of peers, and severe adjustment difficulties (Ladd et al., 2011; Pedersen et al., 2007).

Both types of rejected children are at risk for peer harassment. But as the Biology and Environment box on the following page reveals, rejected-withdrawn children are especially likely to be victimized (Putallaz et al., 2007).

LOOK and LISTEN

Contact a nearby elementary school or a school district office to find out what practices are in place to prevent bullying. Inquire about a written antibullying policy, and request a copy.

Controversial and Neglected Children. Consistent with the mixed peer opinion they engender, controversial children display a blend of positive and negative social behaviors. They are hostile and disruptive, but they also engage in positive, prosocial acts. Even though some peers dislike them, they have qualities that protect them from exclusion. They are usually assertive and dominant, have as many friends as popular children, and are happy with their peer relationships (de Bruyn & Cillessen, 2006; Newcomb, Bukowski, & Pattee, 1993). But like their popular-antisocial and rejected-aggressive counterparts, they often bully agemates to get their way and engage in calculated relational aggression to sustain their dominance (DeRosier & Thomas, 2003; Putallaz et al., 2007). The social status of controversial children often changes over time as agemates react to their mixed behavior.

Perhaps the most surprising finding on peer acceptance is that neglected children, once thought to be in need of treatment, are usually well-adjusted. Although they engage in low rates of interaction and are considered shy by their classmates, most are just as socially skilled as average children. They do not report feeling unhappy about their social life. And when they want to, they can break away from their usual, preferred pattern of playing alone, cooperating well with peers and forming positive, stable friendships (Ladd & Burgess, 1999; Ladd et al., 2011). Consequently, neglected status (like controversial status) is often temporary. Neglected, socially competent children remind us that an outgoing, gregarious personality style is not the only path to emotional well-being. Nevertheless, a few neglected children are socially anxious and poorly skilled and, thus, at risk for peer rejection.

Helping Rejected Children

A variety of interventions exist to improve the peer relations and psychological adjustment of rejected children. Most involve coaching, modeling, and reinforcing positive social skills, such as how to initiate interaction with a peer, cooperate in play, and respond to another child with friendly emotion and approval. Several of these programs have produced gains in social competence and peer acceptance still present from several weeks to a year later (Asher & Rose, 1997; DeRosier, 2007). Combining social-skills training with other treatments increases their effectiveness. Rejected children often are poor students, and their low academic self-esteem magnifies their negative reactions to teachers and classmates. Intensive academic tutoring improves both school achievement and social acceptance (O'Neil et al., 1997).

Still another approach focuses on training in perspective taking and social problem solving (see Chapter 11). But many rejected-aggressive children are unaware of their poor social skills and do not take responsibility for their social failures (Mrug, Hoza, & Gerdes, 2001). Rejected-withdrawn children, in contrast, are likely to develop a *learned-helpless* approach to peer acceptance—concluding, after repeated rebuffs, that they will never be liked (Wichmann, Coplan, & Daniels, 2004). Both types of rejected children need help attributing their peer difficulties to internal, changeable causes.

BIOLOGY and ENVIRONMENT

Bullies and Their Victims

© PAUL BALDESARE/PHOTOFUSION

Many bullies are disliked, or become so, because of their cruelty, but a substantial number are prominent, powerful youngsters, whom peers admire. And chronic victims are often easy targets—physically frail, passive, and rejected by peers.

Follow the activities of aggressive children over a school day, and you will see that they reserve their hostilities for certain peers. A particularly destructive form of interaction is **peer victimization,** in which certain children become targets of verbal and physical attacks or other forms of abuse. What sustains these repeated assault–retreat cycles between pairs of children?

About 20 percent of children are bullies, while 25 percent are repeatedly victimized. Most bullies are boys who use physically, verbally, and relationally aggressive tactics, but a considerable number of girls have bombarded vulnerable classmates with verbal and relational hostility (Cook et al., 2010). In addition to other forms of bullying, gender harassment increases in early adolescence—powerful youths (more often boys) delivering insults of a sexual nature against weaker agemates, heterosexual youths targeting sexual minority peers (Pepler et al., 2006). As bullies move into adolescence, many amplify their attacks through electronic means (Twyman et al., 2010). About 20 to 40 percent of youths have experienced "cyberbullying" through text messages, e-mail, chat rooms, or other electronic tools (Tokunaga, 2010). They often do not report it to parents or adults at school.

Many bullies are disliked, or become so, because of their cruelty. But a substantial number are socially prominent, powerful youngsters, who are broadly admired for their physical attractiveness, leadership, or athletic abilities (Vaillancourt et al., 2010c). In an effort to preserve their high social status, bullies often target already peer-rejected children, whom classmates are unlikely to defend (Veenstra et al., 2010). This helps explain why peers rarely intervene to help victims, and why about 20 to 30 percent of onlookers encourage bullies, even joining in (Salmivalli & Voeten, 2004). Bullying occurs more often in schools where teachers are viewed as unfair and uncaring and where many students judge bullying behaviors to be "OK" (Guerra, Williams, & Sadek, 2011). Indeed, bullies, and the peers who assist them, typically display social-cognitive deficits, including overly high self-esteem, pride in their acts, and indifference to harm done to their victims (Hymel et al., 2010). In a Swedish longitudinal study, early adolescent bullies continued on their antisocial paths: Over half committed crimes (often violent ones) between ages 16 and 24 (Olweus, 2011).

Chronic victims tend to be passive when active behavior is expected. On the playground, they hang around chatting or wander on their own. When bullied, they give in, cry, and assume defensive postures (Boulton, 1999). Biologically based traits—an inhibited temperament and a frail physical appearance—contribute to victimization. But victims also have histories of resistant attachment, overly controlling child rearing, and maternal overprotection—parenting that prompts anxiety, low self-esteem, and dependency, resulting in a fearful demeanor that marks these children as vulnerable (Snyder et al., 2003). Persistent bullying, in turn, engenders social-cognitive deficits (poor perspective taking, viewing peers as generally hostile), further impairing victims' emotional self-regulation and social skills—outcomes that heighten victimization (Hoglund & Leadbeater, 2007; Rosen, Milich, & Harris,2007). As early as kindergarten, victims display adjustment difficulties that may include depression, loneliness, poor school performance, unruly behavior, and school avoidance (Paul & Cillessen, 2003). And like persistent child abuse, victimization is linked to impaired production of cortisol, suggesting a chronically disrupted physiological response to stress (Vaillancourt et al., 2010b).

Aggression and victimization are not polar opposites. One-third to one-half of victims are also aggressive. Occasionally, they retaliate against powerful bullies, who respond by abusing them again—a cycle that sustains their victim status (Kochenderfer-Ladd, 2003). Among rejected children, these bully/victims are the most despised. They often have histories of extremely maladaptive parenting, including child abuse. This combination of highly negative home and peer experiences places them at severe risk for maladjustment (Kowalski, Limber, & Agatston, 2008; Schwartz, Proctor, & Chien, 2001).

Interventions that change victimized children's negative opinions of themselves and that teach them to respond in nonreinforcing ways to their attackers are helpful. Another way to assist victimized children is to help them acquire the social skills needed to form and maintain a gratifying friendship. When children have a close friend to whom they can turn for help, bullying episodes typically end quickly. Anxious, withdrawn children with a close friend have fewer adjustment problems than those with no friends (Fox & Boulton, 2006; Laursen et al., 2007).

Although modifying victimized children's behavior can help, this does not mean that they are to blame. The best way to reduce bullying is to change youth environments (including school, sports programs, recreation centers, and neighborhoods), promoting prosocial attitudes and behaviors. Effective approaches include developing school and community codes against both "traditional" and "cyber" bullying; teaching peer bystanders to intervene and to join forces with other classmates to publicly condemn bullying; enlisting parents' assistance in changing bullies' behaviors; strengthening adult supervision of high-bullying areas in schools such as hallways, lunchroom, schoolyard; and (if necessary) moving socially prominent bullies to another class or school (Kiriakidis & Kavoura, 2010; Leadbeater & Hoglund, 2006; Vaillancourt et al., 2010a).

The U.S. Department of Health and Human Services has launched a media campaign, Stop Bullying Now, www.stopbullyingnow.hrsa.gov, which raises awareness of the harmfulness of bullying through TV and radio public service announcements. It also provides parents, teachers, and students with information on prevention.

As rejected children gain in social skills, teachers must encourage peers to alter their negative opinions. Accepted children often interpret the ambiguous behaviors of disliked agemates negatively, and they selectively recall their negative acts while overlooking their positive ones (Mikami, Lerner, & Lun, 2010; Peets et al., 2007). Consequently, even in the face of contrary evidence, rejected children's negative reputations often persist. Teachers' praise and expressions of liking can modify peer judgments. And building a positive classroom climate through whole-class meetings in which children share in creating classroom rules—including prohibiting exclusion—is also helpful.

Finally, because rejected children's socially incompetent behaviors often originate in a poor fit between the child's temperament and parenting practices, interventions focusing on the child alone may not be sufficient (Bierman & Powers, 2009). As early as the preschool years, rejected children engage in similarly inept communication with parents and with peers (Black & Logan, 1995; Guralnick et al., 2007). Without interventions directed at improving the quality of parent–child interaction, rejected children will continue to practice poor interpersonal skills at home and, as a result, may soon return to their old behavior patterns.

ASK YOURSELF

Review ■ Why are rejected children at risk for maladjustment? What experiences with peers probably contribute to their serious, long-term adjustment problems?

Connect ■ Cite parenting influences on children's social skills, and explain why interventions that focus only on the rejected child are unlikely to produce lasting changes in peer acceptance (see page 619). What changes in parent–child relationships are probably necessary?

Apply ■ Each day on the school bus and during recess, Jodee—a quiet, sensitive fifth grader—was pushed, pelted with gravel, and showered with insults by her classmates. Following the advice of her well-meaning parents, she tried to ignore her tormentors. What factors made Jodee susceptible to peer victimization? How can it be prevented?

Reflect ■ Name several classmates from your high school days who were high in *social prominence*—admired by many peers. Describe these classmates' attributes. Were they also *socially preferred*—that is, peers whom you and your friends liked personally? Explain.

Peer Groups

TAKE A MOMENT... Watch children in the schoolyard or neighborhood, and notice how they often gather in groups of three to a dozen or more. In what ways are members of the same group noticeably alike?

By the end of middle childhood, children display a strong desire for group belonging. They form **peer groups,** collectives that generate unique values and standards for behavior and a social structure of leaders and followers. Whereas friendships contribute to the development of trust, sensitivity, and intimacy, peer groups provide practice in cooperation, leadership, followership, and loyalty to collective goals. Through these experiences, children experiment with and learn about the functioning of social organizations.

First Peer Groups Peer groups organize on the basis of proximity (being in the same classroom) and similarity in sex, ethnicity, academic achievement, popularity, and aggression (Rubin, Bukowski, & Parker, 2006). When groups are tracked for three to six weeks, membership changes very little. When they are followed for a year or longer, substantial change can occur, depending on whether children are reshuffled into different classrooms. When children remain together, 50 to 70 percent of groups consist mostly of the same children from year to year (Cairns, Xie, & Leung, 1998).

The practices of these informal groups lead to a "peer culture" that typically involves a specialized vocabulary, dress code, and place to "hang out." As children develop these exclusive associations, the codes of dress and behavior that grow out of them become more broadly influential. Schoolmates who deviate—by "kissing up" to teachers, wearing the wrong kind of shoes, or tattling on classmates—are often rebuffed, becoming targets of critical glances and comments. These customs bind peers together, creating a sense of group identity.

School-age children evaluate a group's decision to exclude a peer in complex ways. Most view exclusion as wrong, even when they see themselves as different from the excluded child. And with age, children are less likely to endorse excluding someone because of unconventional appearance or behavior. Girls, especially, regard exclusion as unjust, perhaps because they experience it more often than boys (Killen, Crystal, & Watanabe, 2002). But when a peer threatens group functioning, by acting disruptively or by lacking skills to participate in a valued group activity (such as sports), both boys and girls say that exclusion is justified—a perspective that strengthens with age (Killen & Stangor, 2001).

Despite these sophisticated understandings, as we have seen in this and previous chapters, children do exclude unjustly, often using relationally aggressive tactics. Peer groups—at the instigation of socially prominent leaders, who show off their power through skillfully aggressive acts—frequently oust no-longer-"respected" children. Some of these cast-outs, whose own previous hostility toward outsiders reduces their chances of being included elsewhere, turn to other low-status peers with poor social skills (Farmer et al., 2010; Werner & Crick, 2004). Socially anxious children, when ousted, often become increasingly peer-avoidant and thus more isolated (Gazelle & Rudolph, 2004). In either case, opportunities to acquire socially competent behavior diminish.

As excluded children's class participation declines, their academic achievement suffers (Buhs, Ladd, & Herald, 2006). And some aggressive children—especially popular boys—link up with popular, nonaggressive agemates (Bagwell et al., 2000; Farmer et al., 2002). In these groups, mild-mannered children may accept and even support the antisocial acts of their dominant, antisocial associates, who pick fights with other groups or bully weaker children. Consequently, teachers and counselors must target both antisocial and mixed peer groups to reduce peer aggression.

© DAVID ROTH/GETTY IMAGES/TAXI

Peer groups first form in middle childhood. These boys' relaxed body language and similar way of dressing suggest a strong sense of group belonging.

School-age children's desire for group belonging also can be satisfied through formal group ties such as scouting, 4-H, and religious youth groups, where adult involvement holds in check the negative behaviors associated with children's informal peer groups. And through working on joint projects and helping in their communities, children gain in social and moral maturity (Vandell & Shumow, 1999).

Cliques and Crowds

In early adolescence, peer groups become increasingly common and more tightly structured. They are organized into **cliques,** groups of about five to eight members who are friends and, therefore, usually resemble one another in family background, attitudes, values, and interests (Brown & Dietz, 2009). At first, cliques are limited to same-sex members. Among girls but not boys, being in a clique predicts academic and social competence. Clique membership is more important to girls, who use it as a context for expressing emotional closeness (Henrich et al., 2000). By mid-adolescence, mixed-sex cliques become common.

Among Western adolescents attending high schools with complex social structures, often several cliques with similar values form a larger, more loosely organized group called a **crowd.** Unlike the more intimate clique, membership in a crowd is based on reputation and stereotype, granting the adolescent an identity within the larger social structure of the school. Crowds in a typical high school might include "brains" (nonathletes who enjoy academics), "jocks" (who are very involved in sports), "populars" (class leaders who are highly social and involved in activities), "partyers" (who value socializing but care little about schoolwork), "nonconformists" (who like unconventional clothing and music), "burnouts" (who cut school and get into trouble), and "normals" (average to good students who get along with most other peers) (Kinney, 1999; Stone & Brown, 1999).

© THE STAR-LEDGER/BILL PERLMAN/THE IMAGE WORKS

These high school drama club members form a crowd, establishing relationships on the basis of shared interests and abilities. Crowd membership grants them an identity within the larger social structure of the school.

What influences the sorting of teenagers into cliques and crowds? Crowd affiliations are linked to strengths in adolescents' self-concepts, which reflect their abilities and interests (Prinstein & La Greca, 2004). Ethnicity also plays a role. Minority teenagers who associate with an ethnically defined crowd, as opposed to a crowd reflecting their abilities and interests, may be motivated by discrimination in their school or neighborhood. Alternatively, they may have joined the crowd as an expression of a strong ethnic identity (Brown et al., 2008). Family factors are important, too. In a study of 8,000 ninth to twelfth graders, adolescents who described their parents as authoritative tended to be members of "brain," "jock," and "popular" groups that accepted both adult and peer reward systems. In contrast, boys with permissive parents aligned themselves with "partyers" and "burnouts," suggesting lack of identification with adult reward systems (Durbin et al., 1993).

These findings indicate that many peer-group values are extensions of values acquired at home. Once adolescents join a clique or crowd, it can modify their beliefs and behaviors. In research on crowd affiliation and health-risk behaviors, brains were the lowest risk takers, populars and jocks were intermediate, and nonconformists and burnouts were the highest, often engaging in unhealthy eating, substance use, and unprotected sex and agreeing that they would "do anything on a dare" (La Greca, Prinstein, & Fetter, 2001; Mackey & La Greca, 2007). But the positive impact of having academically and socially skilled peers is greatest for teenagers whose own parents are authoritative. And the negative impact of associating with antisocial, drug-using agemates is strongest for teenagers whose parents use less effective child-rearing styles (Mounts & Steinberg, 1995). In sum, family experiences affect the extent to which adolescents become like other group members over time.

As interest in dating increases, boys' and girls' cliques come together. Mixed-sex cliques provide boys and girls with models for how to interact with the other sex and a chance to do so without having to be intimate (Connolly et al., 2004). Gradually, the larger group divides into couples, several of whom spend time going out together. By late adolescence, when boys and girls feel comfortable enough about approaching each other directly, the mixed-sex clique disappears (Connolly & Goldberg, 1999).

Crowds also decline in importance. As adolescents settle on personal values and goals, they no longer feel a need to broadcast, through dress, language, and preferred activities, who they are. From tenth to twelfth grade, about half of young people switch crowds, mostly in favorable directions (Strouse, 1999). "Brains" and "normal" crowds grow and deviant crowds lose members as teenagers focus more on their future.

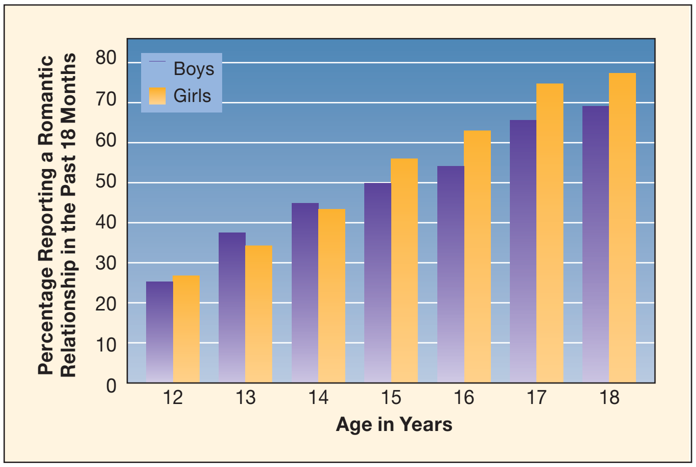

FIGURE 15.3 Increase in romantic relationships during adolescence. More than 16,000 U.S. youths responded to an interview in which they indicated whether they had been involved in a romantic relationship during the past 18 months. At age 12, about one-fourth of young people reported romantic involvement, a figure that rose to about three-fourths at age 18. (Adapted from Carver, Joyner, & Udry, 2003.)

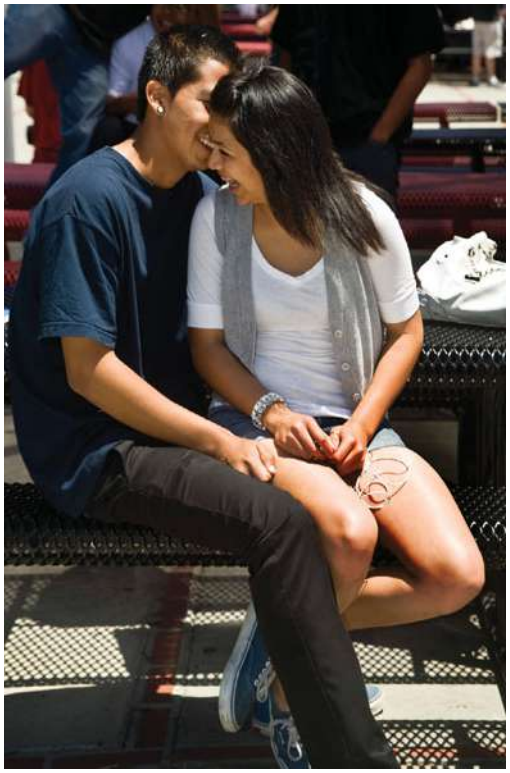
Dating

The hormonal changes of puberty increase sexual interest (see Chapter 5), but cultural expectations determine when and how dating begins. Asian youths start dating later and have fewer dating partners than young people in Western societies, which tolerate and even encourage early romantic involvements from middle school on (see Figure 15.3). At age 12 to 14, these relationships are usually casual, lasting only five months on average. By age 16, they have become steady relationships, typically continuing for about two years (Carver, Joyner, & Udry, 2003). This change reflects transformations in teenagers' dating goals: Early adolescents tend to mention recreation and achieving peer status as reasons for dating. By late adolescence, as young people are ready for greater intimacy, they seek dating partners who offer personal compatibility, companionship, affection, and social support (Collins & Van Dulmen, 2006a; Meier & Allen, 2009).

The achievement of intimacy between dating partners typically lags behind that between friends. And positive relationships with parents and friends contribute to the development of warm romantic ties, whereas conflict-ridden parent–adolescent and peer relationships forecast hostile dating interactions (Furman & Collins, 2009; Linder & Collins, 2005). Recall from Chapter 10 that according to ethological theory, early attachment bonds lead to an *internal working model,* or set of expectations about attachment figures, that guides later close relationships. Consistent with this idea, secure attachment to parents in infancy and childhood—together with recollections of that security in adolescence—predicts quality of teenagers' and young adults' friendships and romantic ties (Collins & Van Dulmen, 2006b; Collins, Welsh, & Furman, 2009). In a study of high school seniors, secure models of attachment and supportive interactions with parents predicted secure models of friendship, which, in turn, were related to the security of romantic relationships (Furman et al., 2002).

Perhaps because early adolescent dating relationships are shallow and stereotyped, early, frequent dating is related to drug use, delinquency, and poor academic achievement (Eaton et al., 2007; Miller et al., 2009). These factors, along with a history of uninvolved parenting and aggression in family and peer relationships, increase the likelihood of dating violence. About 10 to 20 percent of adolescents are physically or sexually abused by dating partners, with boys and girls equally likely to report being victims, and violence by one partner is often returned by the other (Cyr, McDuff, & Wright, 2006; Williams et al., 2008). Mental health consequences are severe, including increased anxiety, depression, suicide attempts, risky sexual behavior, and—in girls—unhealthy weight control (vomiting and use of laxatives) (Carver, Joyner, & Udry, 2003; Silverman et al., 2001; Wekerle & Avgoustis, 2003). Furthermore, whereas early-adolescent boys who date gain in status among same-sex peers, girls often experience conflict due to competition and jealousy of other girls. For all these reasons, sticking with group activities, such as parties and dances, before becoming involved with a steady boyfriend or girlfriend is best for young teenagers.



© SPENCER GRANT/PHOTOEDIT

As long as dating does not begin too soon, it extends the benefits of adolescent friendships, promoting sensitivity, empathy, self-esteem, and identity development.

Gay and lesbian youths face special challenges in initiating and maintaining visible romances. Their first dating relationships seem to be short-lived and to involve little emotional commitment, but for reasons that differ from those of heterosexuals: They fear peer harassment and rejection (Diamond & Lucas, 2004). Recall from Chapter 5 that because of intense prejudice, homosexual adolescents often retreat into heterosexual dating. In addition, many have difficulty finding a same-sex partner because their gay and lesbian peers have not yet come out. Often their first contacts with other sexual-minority youths occur in support groups, where they are free to date publicly and can discuss concerns about coming out (Diamond, 2003).

As long as it does not begin too soon, dating provides lessons in cooperation, etiquette, and dealing with people in a wide range of situations. Among older teenagers, close romantic ties promote sensitivity, empathy, self-esteem, social support, and identity development. In addition, teenagers' increasing capacity for interdependence and compromise within dating probably enhances the quality of other peer relationships (Collins, Welsh, & Furman, 2009).

Still, about half of first heterosexual romances do not survive graduation, and those that do usually become less satisfying (Shaver, Furman, & Buhrmester, 1985). Because young people are still forming their identities, high school couples often find that they have little in common later. Nevertheless, warm, caring romantic ties in adolescence can have long-term implications. They are positively related to gratifying, committed relationships in early adulthood (Meier & Allen, 2009).

Peer Pressure and Conformity

Conformity to peer pressure is greater during adolescence than in childhood or early adulthood—a finding that is not surprising when we consider how much time teenagers spend together. But contrary to popular belief, adolescence is not a period in which young people blindly do what their peers ask. Peer conformity is a complex process that varies with the adolescent's age, current situation, need for social approval, and culture.

SOCIAL ISSUES: HEALTH

Adolescent Substance Use and Abuse

Teenage alcohol and drug use is pervasive in industrialized nations. According to the most recent nationally representative survey of U.S. high school students, by tenth grade, 33 percent of U.S. young people have tried smoking, 59 percent drinking, and 38 percent at least one illegal drug (usually marijuana). At the end of high school, 15 percent smoke cigarettes regularly and 16 percent have engaged in heavy drinking during the past month. About 24 percent have tried at least one highly addictive and toxic substance, such as amphetamines, cocaine, phencyclidine (PCP), Ecstasy (MDMA), inhalants, heroin, sedatives (including barbiturates), or OxyContin (a narcotic painkiller) (Johnston et al., 2010).

These figures represent a substantial decline since the mid-1990s, probably resulting from greater societal focus on the hazards of drug taking. But use of some substances—marijuana, inhalants, sedatives, and OxyContin—has risen slightly in recent years (Johnston et al., 2010). Other drugs, such as LSD, PCP, and Ecstasy, have made a comeback as adolescents' knowledge of their risks faded.

In part, drug taking reflects the sensation seeking of the teenage years. But adolescents also live in drug-dependent cultural contexts. They see adults relying on caffeine to stay alert, alcohol and cigarettes to cope with daily hassles, and other remedies to relieve stress, depression, and physical discomfort. And compared to a decade or two ago, today doctors more often prescribe—and parents frequently seek—medication to treat children's problems (Olfman & Robbins, 2012). In adolescence, these young people may readily "self-medicate" when stressed.

Most teenagers who dabble in alcohol, tobacco, and marijuana are not headed for a life of addiction. These *minimal experimenters* are usually psychologically healthy, sociable, curious young people (Shedler & Block, 1990). As Figure 15.4 shows, tobacco and alcohol use is somewhat greater among European than among U.S. adolescents, perhaps because European adults more often smoke and drink. But illegal drug use is far more prevalent among U.S. teenagers. A greater percentage of American young people live in poverty, which is linked to family and peer contexts that promote illegal drug use. At the same time, use of diverse drugs is lower among African Americans than among Hispanic and Caucasian Americans; Native-American youths rank highest in drug taking (Johnston et al., 2010; Wallace et al., 2003). Researchers have yet to explain these variations.

Adolescent experimentation with any drug should not be taken lightly. Because most drugs impair perception and thought processes, a single heavy dose can lead to permanent injury or death. And a worrisome minority of teenagers move from substance *use* to *abuse*—taking drugs regularly, requiring increasing amounts to achieve the same effect, moving to harder substances, and using enough to impair their ability to meet school, work, or other responsibilities. Three percent of high school seniors are daily drinkers, and 5 percent have taken illegal drugs on a daily basis over the past month (Johnston et al., 2010).

Correlates and Consequences of Adolescent Substance Abuse

Unlike experimenters, drug abusers are seriously troubled young people. Longitudinal evidence reveals that their impulsive, disruptive, hostile

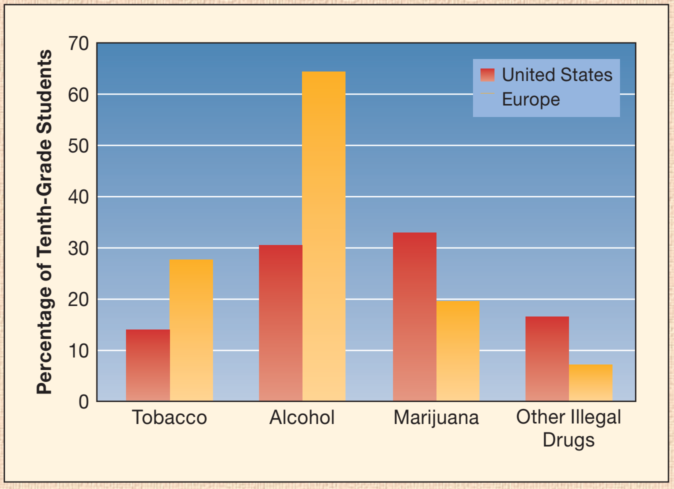


FIGURE 15.4 Tenth-grade students in the United States and Europe who have used various substances. Rates for tobacco and alcohol are based on any use in the past 30 days. Rates for marijuana and other illegal drugs are based on any lifetime use. Tobacco use and alcohol use are greater for European adolescents, whereas illegal drug use is greater for U.S. adolescents. (Adapted from CAN, 2007; Johnston et al., 2010.)

A study of several hundred U.S. middle and high school students revealed that adolescents felt greatest pressure to conform to the most obvious aspects of the peer culture—dress, grooming, and participation in social activities. Peer pressure to engage in proadult behavior, such as cooperating with parents and getting good grades, was also strong (Brown, Lohr, & McClenahan, 1986). Many teenagers said that their friends actively discouraged antisocial acts. In similar research conducted in Singapore, a culture that emphasizes family loyalty, outcomes were much the same, except that peer pressure to meet family and school obligations exceeded pressure to join in peer-culture pursuits (Sim & Koh, 2003). As these findings reveal, adults and peers often act in concert, toward desirable ends!

Resistance to peer pressure strengthens with age, though wide individual differences exist (Steinberg & Monahan, 2007; Sumter et al., 2009). Personal characteristics make a difference: Young people who feel competent and worthwhile, who score low in sensation seeking and in need for peer approval, and who are more effective decision makers are less likely style is often evident in early childhood, and they engage in other high-risk behaviors and are inclined to express their unhappiness through antisocial acts. Compared with other young people, their drug taking starts earlier and may have genetic roots (Dick, Prescott, & McGue, 2008; Tarter, Vanyukov, & Kirisci, 2008). But environmental factors also contribute. These include low SES, family mental health problems, parental and older sibling drug and alcohol abuse, lack of parental warmth and involvement, physical and sexual abuse, and poor school performance. Especially among teenagers with family difficulties, encouragement from friends who use and provide drugs increases substance abuse (Goldstein, Davis-Kean, & Eccles, 2005; Ohannessian & Hesselbrock, 2008; Prinstein, Boergers, & Spirito, 2001).

Teenagers who depend on alcohol and hard drugs to deal with daily stresses fail to learn responsible decision-making skills and alternative coping techniques. They show serious adjustment problems, including chronic anxiety, depression, and antisocial behavior, that are both cause and consequence of heavy drug taking (Kassel et al., 2005; Simons-Morton & Haynie, 2003). And they often enter into marriage, childbearing, and the work world prematurely and fail at these challenges—painful outcomes that further promote addictive behavior.

Prevention and Treatment

School and community programs that reduce drug experimentation typically combine several features:

- They promote effective parenting, including monitoring of teenagers' activities.
- They teach skills for resisting peer pressure.
- They reduce the social acceptability of drug taking by emphasizing health and safety risks (Cuijpers, 2002; Stephens et al., 2009).

But given that adolescent drug taking is widespread, interventions that prevent teenagers from harming themselves and others when they do experiment are essential. Many communities offer weekend on-call transportation services that any young person can contact for a safe ride home, with no questions asked. Providing appealing substitute activities, such as drug-free dances and sports activities, is also helpful.

Because drug abuse has different roots than occasional use, different prevention strategies are required. One approach is to work with parents early, reducing family adversity and improving parenting skills, before children are old enough for drug involvement (Velleman, Templeton, & Copello, 2005). Programs that teach at-risk teenagers effective strategies for handling life stressors and that build competence through community service reduce alcohol and drug abuse, just as they reduce teenage pregnancy (see Chapter 5).

When an adolescent becomes a drug abuser, family and individual therapy are generally needed to treat maladaptive parent–child relationships, impulsivity, low-self-esteem, anxiety, and depression. Academic and vocational training to improve life success also helps. But even comprehensive programs have alarmingly high relapse rates—from 35 to 85 percent (Brown & Ramo, 2005; Sussman, Skara, & Ames, 2008). One recommendation is to start treatment gradually, through support-group sessions that focus on reducing drug taking. Within the group, interveners can address teenagers' low motivation to change and resistance to adult referral, which they often view as an infringement on their personal freedom. Such brief interventions lessen drug taking in the short term (Myers et al., 2001). Modest improvement may boost the young person's sense of self-efficacy for behavior change and, as a result, increase motivation to make longer-lasting changes through intensive treatment.

Teenagers enjoy a party sponsored by Drug Free Youth in Town (DFYIT), a substance abuse prevention program. DFYIT trains high school students as peer educators, who teach middle school students strategies for resisting peer pressure.

to fall in line with peers who engage in early sex, delinquency, and frequent drug use (Crockett, Raffaelli, & Shen, 2006; McIntyre & Platania, 2009) (see the Social Issues: Health box above).

Authoritative parenting is also influential. When parents are supportive and exert appropriate oversight, teenagers respect them—an attitude that acts as an antidote to unfavorable peer pressure (Dorius et al., 2004). In contrast, adolescents whose parents exert either too much or too little control tend to be highly peer-oriented. Youths who bend easily to peer influence display wide-ranging problems, including unstable friendships, aggression, delinquency, and declining peer popularity and increasing depressive symptoms over time (Allen, Porter, & McFarland, 2006).

Before we turn to the impact of media on children and adolescents, you may find it helpful to examine the Milestones table on page 628, which summarizes the development of peer relations.

Milestones

Development of Peer Relations

AGE	PEER SOCIABILITY	FRIENDSHIP	PEER GROUPS
Birth–2 years	• Isolated social acts increase and are gradually replaced by coordinated interaction.	• Mutual relationships with familiar peers emerge.	
2½–6 years	• Parallel play appears, remains stable, and becomes more cognitively mature. • Cooperative play, especially sociodramatic play, increases. • Rough-and-tumble play emerges.	• Friendship is viewed concretely, in terms of play and sharing toys. 	
7–11 years	• Peer communication skills improve as a result of improved perspective taking and awareness of emotional display rules. • Ability to understand the complementary roles of several players improves, permitting the transition to rule-oriented games. • Peer interaction becomes more prosocial. • Rough-and-tumble play increases.	• Friendship is based on mutual trust and assistance. • Interaction between friends becomes more prosocial. • Number of close friends declines. • Friends increasingly resemble one another in personality, popularity, academic achievement, prosocial behavior, and judgments of other people.	• Peer groups emerge. • Dominance hierarchies become increasingly stable.
12–18 years	• Peer interaction becomes more cooperative. • Rough-and-tumble play declines. • Time spent with peers increases, exceeding that with any other social partners. 	• Friendship is based on intimacy, mutual understanding, and loyalty. • Friends tend to be alike in identity status, educational aspirations, political beliefs, and deviant behavior. • Young people choose some friends who differ from themselves. • Number of close friends declines further. • Romantic relationships emerge and gradually last longer.	• Peer groups become more tightly structured, organized around cliques. • Cliques with similar values form crowds. • As interest in dating increases, mixed-sex cliques form. • Mixed-sex cliques and crowds gradually diminish. • Resistance to peer pressure gradually strengthens.

Note: These milestones represent overall age trends. Individual differences exist in the precise age at which each milestone is attained.

ASK YOURSELF

Review ■ Describe the distinct positive functions of friendships, cliques, and crowds. What factors lead some friendships and peer-group ties to be harmful?

Connect ■ How might gender intensification, discussed on page 550 in Chapter 13, contribute to the shallow quality of early adolescent dating relationships?

Apply ■ Thirteen-year-old Mattie's parents are warm, firm in their expectations, and consistent in monitoring her activities. Is Mattie likely to succumb to unfavorable peer pressure? Explain.

Reflect ■ How did family experiences influence your crowd membership in high school? How did your crowd membership influence your behavior?

Media

- Discuss the influence of television on children's development.
- Discuss computer, cell phone, and Internet use by children and adolescents, noting benefits and concerns.

During the past half-century, the role of media in the lives of children and adolescents has undergone "revolutionary change" (Comstock & Scharrer, 2006). Although television remains the dominant form of youth media, computers now exist in most American homes and in virtually all school classrooms (Rideout, Foehr, & Roberts 2010). Among older school-age children and adolescents, time consumed by cell-phone use may eventually catch up with TV: The cell phone has become the favored channel of communication between teenagers and their friends, and young people also use it for diverse entertainment purposes, including listening to music, playing games, and accessing TV programs.

Today, U.S. 8- to 18-year-olds devote an average of 7½ hours a day (a dramatic 53 hours a week) to entertainment media of all kinds. And because many youths engage in extensive media multitasking (see page 293 in Chapter 7), they actually pack in a total of 10¾ hours of daily media content. Overall media use rises from middle childhood into early adolescence, largely due to increased TV watching and time spent listening to music on cell phones or MP3 players (see Figure 15.5). Heavy users of one medium tend to be heavy users of others (Rideout, Foehr, & Roberts, 2010). A burgeoning research literature addresses the wide-ranging impact of media on development.

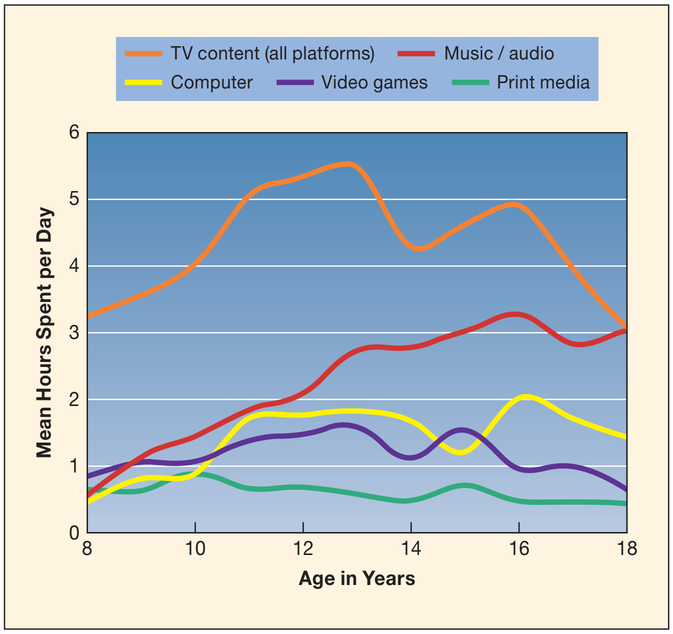

FIGURE 15.5 Time spent by U.S. 8- to 18-year-olds with various media by age. A survey of a large, nationally representative sample of U.S. young people revealed that watching TV and listening to music largely accounted for the overall rise in media use from middle childhood into early adolescence. Print media (magazines and newspapers) consumed the least media time. (From "Generation M2: Media in the Lives of 8- to 18-Year-Olds," (#8010), The Henry J. Kaiser Family Foundation, January 2010. This information was reprinted with permission from the Henry J. Kaiser Family Foundation, www.kff.org.)

Television

Exposure to television is almost universal in the industrialized world. Nearly all homes have at least one television set, and most have two or more. Average time spent watching is remarkably similar across developed nations, and young people in the developing world are not far behind (International Telecommunications Union, 2010; Scharrer & Comstock, 2003).

Widespread concern about television's impact on children's development is certainly warranted. In an unusual investigation, residents of a small Canadian town were studied just before TV reception became available in their community and again two years later. Striking changes occurred: in school-age children, a decline in reading ability and creative thinking, a rise in gender-stereotyped beliefs, and an increase in verbal and physical aggression during play; in adolescents, a sharp drop in community participation (Williams, 1986).

But television has equal potential for good. If the content of TV programming were improved and adults capitalized on it to enhance children's interest in their everyday worlds, television could be a powerful, cost-effective means of strengthening cognitive, emotional, and social development.

How Much Television Do Children View?

Large surveys reveal that American children first become viewers in early infancy. About 40 percent of U.S. 3-month-olds regularly watch either TV or videos. This figure rises to 90 percent by age 2—a period in which toddlers have difficulty applying what they see on the screen to their everyday experiences (return to page 237 in Chapter 6 to review the *video deficit effect*). Between 2 and 6 years, the typical U.S. preschooler watches from 1½ to 2⅔ hours a day, depending on the survey (Rideout & Hamel, 2006; Scharrer & Comstock, 2003; Zimmerman, Christakis, & Meltzoff, 2007). Viewing time increases to an average of 3½ hours a day in middle childhood. In early adolescence, it rises further to more than 5 hours a day, as teenagers increasingly acquire MP3 players and cell phones with Internet connections that enable easy access to TV programs (Rideout, Foehr, & Roberts, 2010). In mid- to late adolescence, time devoted to TV diminishes to 3 to 4 hours a day.

© SHUTTERSTOCK

A television placed in a child's bedroom greatly magnifies time spent watching TV. Extensive TV viewing is linked to family, peer, and health difficulties.

These figures reveal that each week, U.S. preschoolers spend about 10 to 18 hours, school-age children about 24 hours, and adolescents about 32 hours watching TV. When we consider these figures, children and adolescents devote more time to TV than to most other waking activities, including parent and peer interaction, physical activity, computer use, homework, and reading. And when quantity of viewing during school holidays and summer vacations is factored in, the typical child's annual TV viewing comes close to, and the adolescent's exceeds, amount of time spent in school.

Children vary in their attraction to television. From early childhood on, boys watch slightly more than girls. Low-SES, African-American, and Hispanic children also are more frequent viewers, and they are more likely to live in homes where the TV is left on most of the time, even if no one is watching (Rideout, Foehr, & Roberts, 2010). For many such families, perhaps few alternative, affordable forms of entertainment are available in their neighborhoods. Also, parents with limited education are more likely to engage in practices that heighten TV viewing, including eating family meals in front of the set and failing to limit children's TV access (Hesketh et al., 2007).

About one-third of U.S. preschoolers and 70 percent of school-age children and adolescents have a TV set in their bedroom; these children spend from 40 to 90 more minutes per day watching than agemates without one. And if parents watch a lot of TV, their children usually do, too (Rideout & Hamel, 2006; Rideout, Foehr, & Roberts, 2010). Extensive TV viewing is associated with family, peer, and health difficulties, perhaps because highly stressed parents and children use it as an escape (Anderson et al., 1996).

Television and Social Learning

Since the 1950s, researchers and public citizens have been concerned about television's influence on the attitudes and behaviors of young viewers. Most studies address the impact of TV violence. Others focus on the power of TV to teach undesirable gender and ethnic stereotypes and consumerism. At the same time, research confirms TV's potential for enhancing children's prosocial behavior.

Aggression. In the United States, 57 percent of TV programs between 6 A.M. and 11 P.M. contain violent scenes, often portraying repeated physically aggressive acts that go unpunished. Victims of TV violence are rarely shown experiencing serious harm, and few programs condemn violence or depict other ways of solving problems (Center for Communication and Social Policy, 1998). In reality TV shows, verbally and relationally aggressive acts are particularly frequent (Coyne, Robinson, & Nelson, 2010). And violent content is 9 percent above average in children's programming, with cartoons being the most violent.

Reviewers of thousands of studies—using a wide variety of research designs, methods, and participants from diverse cultures—have concluded that TV violence increases the likelihood of hostile thoughts and emotions and of verbally, physically, and relationally aggressive behavior (Comstock & Scharrer, 2006; Ostrov, Gentile, & Crick, 2006). Even a brief dose has immediate effects: In laboratory research, 15 minutes of mildly violent programming heightened aggression in at least one-fourth of viewers (Anderson & Bushman, 2002). Although young people of all ages are susceptible, preschool and young school-age children are especially likely to imitate TV violence because they believe that much TV fiction is real and accept what they see uncritically.

Violent programming not only creates short-term difficulties in parent and peer relations but also has lasting negative consequences. In several longitudinal studies, time spent watching TV in childhood and early adolescence predicted aggressive behavior (including seriously violent acts) in late adolescence and early adulthood, after other factors linked to TV viewing (such as prior child and parent aggression, IQ, parent education, family income, and neighborhood crime) were controlled (see Figure 15.6) (Graber et al., 2006; Huesmann, 1986; Huesmann et al., 2003; Johnson et al., 2002). Aggressive children and adolescents have a greater appetite for TV and other media violence. And boys devote more time to violent media than girls, in part because of male-oriented themes of conquest and adventure and use of males as lead characters. Even in nonaggressive children, violent TV sparks hostile

LOOK and LISTEN

Watch a half-hour of Saturday morning cartoons and a prime-time movie on TV, and tally the number of violent acts, including those that go unpunished. How often did violence occur in each type of program? What do young viewers learn about the consequences of violence?

thoughts and behavior; its impact is simply less intense (Bushman & Huesmann, 2001).

Furthermore, television violence "hardens" children to aggression, making them more willing to tolerate it in others (Anderson et al., 2003). Heavy viewers believe that there is much more violence in society than there actually is—an effect that is especially strong for children who perceive televised aggression to be relevant to their own lives (Donnerstein, Slaby, & Eron, 1994). As these responses indicate, exposure to violent TV modifies children's attitudes toward social reality so that they increasingly match TV images.

Ethnic and Gender Stereotypes. Although educational programming for children is sensitive to issues of equity and diversity, commercial entertainment TV conveys ethnic and gender stereotypes. African Americans, Hispanics, and other ethnic minorities are underrepresented. When minorities do appear, they are more likely than whites to be depicted in secondary or lower-status roles, such as domestic workers or unskilled laborers, and as lawbreakers (Dixon & Azocar, 2006; Scharrer & Comstock, 2003).

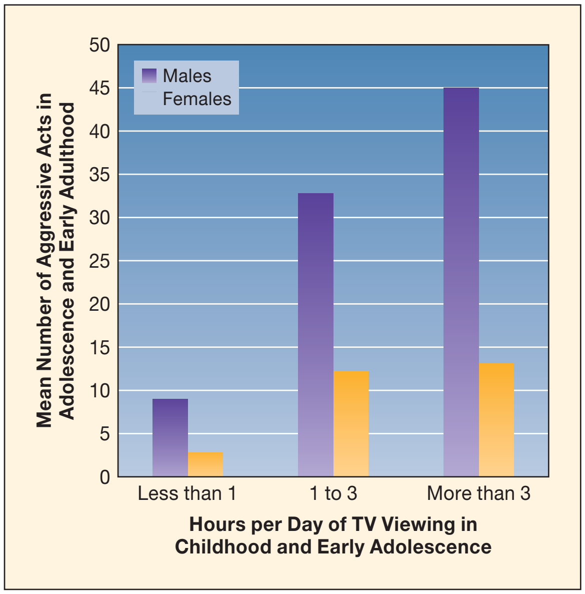

FIGURE 15.6 Relationship of television viewing in childhood and early adolescence to aggressive acts in adolescence and early adulthood. Interviews with more than 700 parents and youths revealed that the more TV watched in childhood and early adolescence, the greater the annual number of aggressive acts committed by the young person, as reported in follow-up interviews at ages 16 and 22. (Adapted from Johnson et al., 2002.)

Similarly, women appear less often than men, especially as main characters. Compared with two decades ago, today's female characters are more often involved in careers. But they continue to be portrayed as young, attractive, caring, emotional, victimized, and in subordinate family and nonprofessional roles. Furthermore, women are often sexualized, shown in scanty or provocative clothing (Collins, 2011; Signorielli, 2001). In contrast, men are depicted as dominant and powerful. Gender stereotypes are especially prevalent in cartoons, music television (MTV), and other entertainment programs for children and youths.

TV viewing is linked to gender-stereotyped attitudes and behaviors in children and adolescents, including reduced self-esteem and career aspirations, negative body image, and disordered eating in girls (American Psychological Association, 2010; Cole & Daniel, 2005; Rivadeneyra & Ward, 2005). In contrast, positive TV portrayals of women and ethnic minorities lead to more favorable views and greater willingness to form ethnically diverse friendships (Calvert et al., 2003; Graves, 1993).

Consumerism. The marketing industry aimed at selling products to youths—toys, games, foods, clothing, and a host of other items—has exploded, exposing U.S. children and adolescents to tens of thousands of TV commercials each year (American Academy of Pediatrics, 2009). TV ads are rife with gender stereotypes—depicting toys and other products as gender-specific, boys as active and competitive, girls as calm and quiet, and men and women in stereotypical roles (Kahlenberg & Hein, 2010; Paek, Nelson, & Vilela, 2010).

By age 3, children can distinguish an obvious TV ad from regular programming by its loudness, fast-paced action, and sound effects. But because many children's shows contain characters and props that are themselves products (dolls, puppets, action figures, and their accessories), the boundary between programs and commercials is blurred. Furthermore, preschoolers and young elementary school children seldom grasp the selling purpose of TV ads; they think that commercials are meant to help viewers. Around age 8 or 9, most children understand that commercials aim to sell, and by age 11, they realize that advertisers will resort to clever techniques to achieve their goals (Kunkel, 2001). Nevertheless, even older children and adolescents find many commercials alluring. And parents often underestimate the influence of TV advertising on their children (Baiocco, D'Alessio, & Laghi, 2009).

Research suggests that heavy bombardment of children with advertising contributes to a variety of child and youth problems, including family stress, overweight and obesity, materialism, and substance use. In recent surveys of adults that included many parents, over 90 percent reported that youth-directed ads greatly increase children's nagging of parents to buy items, giving rise to family conflict (Linn, 2005). Furthermore, the greater adolescents' exposure to cigarette and alcohol ads—often designed to appeal to them through youthful characters, upbeat music, and party scenes—the more likely they are to smoke and drink (Austin, Chen, & Grube, 2006; Smith & Atkin, 2003).

Prosocial Behavior. Television that includes acts of cooperating, helping, and comforting can increase children's prosocial behavior. In one study, researchers asked more than 500 second to sixth graders to name their favorite educational TV shows and say what they learned from them. The children not only named many prosocial programs but also accurately described the lessons the programs conveyed (Calvert & Kotler, 2003). Much TV, however, mixes prosocial and antisocial messages. Prosocial programs promote children's kind and helpful acts only when they are free of violent content (Hearold, 1986).

Television, Academic Learning, and Imagination Since the early days of television, educators have been interested in its potential for strengthening academic skills, especially among low-SES children. *Sesame Street,* especially, was created to foster children's learning. It uses lively visual and sound effects to stress basic literacy and number concepts and puppet and human characters to teach general knowledge, emotional and social understanding, and social skills. Today, *Sesame Street* is broadcast in 140 countries, making it the most widely viewed children's program in the world (Sesame Workshop, 2009).

Time devoted to watching children's educational programs is associated with gains in early literacy and math skills and to academic progress in elementary school (Ennemoser & Schneider, 2007; Linebarger et al., 2004; Wright et al., 2001). Consistent with these findings, one study reported a link between preschool viewing of *Sesame Street* and other similar educational programs and getting higher grades, reading more books, and placing more value on achievement in high school (Anderson et al., 2001).

Sesame Street has modified its previous format of presenting quick, disconnected bits of information in favor of more leisurely episodes with a clear story line (Truglio, 2000). Children's programs with slow-paced action and easy-to-follow narratives, such as *Arthur & Friends, The Magic School Bus,* and *Wishbone,* lead to more elaborate make-believe play in early childhood and to greater recall of program content and gains in vocabulary and reading skills in the early elementary school grades than programs that simply provide information (Linebarger & Piotrowski, 2010; Singer & Singer, 2005). Narratively structured educational TV eases processing demands, freeing up children's working-memory resources for applying program content to real-life situations.

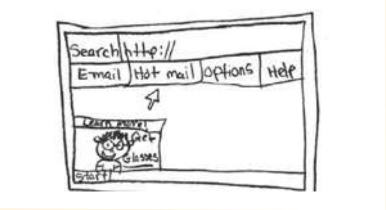
Does extensive TV exposure take children away from worthwhile activities? Persistent background TV distracts infants and preschoolers from their play, diminishing time spent in focused attention and involvement with a set of toys (Courage & Howe, 2010; Schmidt et al., 2008). Educational programs, as previously noted, are beneficial, but watching entertainment TV—especially heavy viewing—detracts from children's and adolescents' reading time, school success, and social experiences (Ennemoser & Schneider, 2007; Huston et al., 1999; Wright et al., 2001). In a survey of U.S. parents of over 48,000 6- to 17-year-olds, children and adolescents with a TV in their bedroom (a sign of especially high viewing time) were less likely to experience regular family meals, care about doing well in school, participate in extracurricular activities and community service, and get enough nightly sleep (Sisson et al., 2011). They also more often displayed problematic social behaviors, including frequent arguing, disobedience, meanness to others, and sullenness or irritability.

Computers, Cell Phones, and the Internet

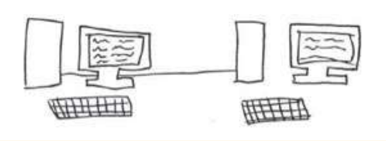
Unlike TV, computers and cell phones offer *interactive* media forms, through a wide range of learning, entertainment, and communication tools (Greenfield & Yan, 2007). More than 90 percent of U.S. children and adolescents live in homes with one or more computers, 80 percent of which have an Internet connection, usually a high-speed link. And virtually all U.S. public schools have integrated computers into their instructional programs and can access the Internet—trends also evident in other industrialized nations. Although higher-SES homes are more likely to have computers, over 85 percent of U.S. lower-SES families with school-age children and adolescents now have them, often with Internet access (Rideout, Foehr, & Roberts, 2010; U.S. Census Bureau, 2011b). Still, only a minority of poverty-stricken families have a home computer.

Recent survey evidence reveals that U.S. children and adolescents, on average, use the computer a half-hour a day for schoolwork and 1½ hours for pleasure—visiting social networking sites, surfing the Web, communicating by instant-messaging or e-mail, and accessing music and video games. Computer time increases with age (Rideout, Foehr, & Roberts, 2010; Roberts, Foehr, & Rideout, 2005). Most parents say they purchased a computer to enrich their child's education; more than one-third of American school-age children and adolescents have a computer in their bedroom. At the same time, parents express great concern about the influence of violent video games and of the Internet (Media Awareness Network, 2001; Rideout & Hamel, 2006).

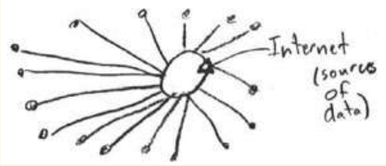
Yet, regardless of the extent of their Internet use, not until ages 10 to 11 do children acquire an adult-level understanding of the technical complexity of the Internet as a networklike system linking a computing center with many computers (see Figure 15.7). This technical grasp is important, as it precedes and probably contributes to sophisticated knowledge of social risks of the Internet (exposure to pornography, theft of personal information, attacks by hackers) and of protection strategies (firewalls, filtering programs, password protection), which is attained around age 12 to 13 (Yan, 2006). Let's see how computers affect academic and social development.



(a) Minimal Understanding



(b) Partial Understanding



(c) Sophisticated Understanding

FIGURE 15.7 Three children's drawings of the Internet, reflecting increased technical understanding with age. When elementary school children were asked to describe and draw a picture of the Internet, most children younger than age 10 revealed either a minimal understanding (viewed the Internet as one computer) or a partial understanding (viewed the Internet as a few connected computers). Most 10- and 11-year-olds had a sophisticated understanding of the Internet as a networklike system in which computing centers link with multiple computers. (From Z. Yan, 2006, "What Influences Children's and Adolescents' Understanding of the Complexity of the Internet?" *Developmental Psychology, 42,* p. 421. Copyright © 2006 by the American Psychological Association. Reprinted with permission of the American Psychological Association.)

Computers and Academic Learning

Computers can have rich educational benefits. Children as young as age 3 enjoy computer activities and are able to use the mouse and type simple keyboard commands. In classrooms, small groups often gather around computers, and children more often collaborate in computer activities than in other pursuits (Svensson, 2000).

In childhood and adolescence, nongame computer use is associated with literacy progress (Calvert et al., 2005; OECD, 2005). Using the computer for word processing enables children to write freely, experimenting with letters and words without having to struggle with handwriting. Because they can revise their text's meaning and style and also check their spelling, they worry less about making mistakes. As a result, their written products tend to be longer and of higher quality. Often children jointly plan, compose, and revise text, learning from one another (Clements & Sarama, 2003).

As children get older, they increasingly use the computer for schoolwork, mostly to search the Web for information needed for school projects and to prepare written assignments—activities linked to improved academic achievement (Attewell, 2001; Judge, Puckett, & Bell, 2006). The more low-SES middle-school students use home computers to access the Internet for information gathering (either for school or for personal interests), the better their subsequent reading achievement and school grades (Jackson et al., 2006, 2011a). Perhaps those who use the Web to find information also devote more time to reading, given that many Web pages are heavily text-based.

The learning advantages of computers raise concerns about a "digital divide" between SES and gender groups. Poverty-stricken children are least likely to have home computers and Internet access. And low-SES children who do have computer Internet access devote less time to it than their higher-SES counterparts, although they compensate to some degree by going online more often on their cell phones (Lenhart et al., 2010). By the end of elementary school, boys spend more time with computers than girls and use computers somewhat differently. Boys, for example, more often connect to the Internet to download games and music, trade and sell things, and create Web pages. Girls emphasize information gathering and social networking (Jackson et al., 2008; Rideout, Foehr, & Roberts, 2010). Furthermore, in a survey of a large, nationally representative sample of Canadian 15- and 16-year-olds, boys more often than girls engaged in writing computer programs, analyzing data, and using spreadsheets and graphics programs. And many more boys than girls rated their computer skills as "excellent" (Looker & Thiessen, 2003). Schools need to ensure that girls and economically disadvantaged students have many opportunities to benefit from the diverse, cognitively enriching aspects of computer technology.

© JOCHEN TACK/ALAMY

Playing speed-and-action video games may improve these children's selective attention and spatial skills. But extensive game playing is negatively related to school performance and is associated with increased hostility and aggression, especially in boys.

Video Games Children and adolescents make extensive use of home computers for entertainment purposes, including video games. On average, U.S. school-age and adolescent boys spend nearly one-third of their computer time playing games—three times as much as girls (Rideout, Foehr, & Roberts, 2010). Most video games emphasize speed and action in violent plots in which children advance by shooting at and evading enemies. Young people also play complex exploratory and adventure games, generally with themes of conquest and aggression, and sports games, such as football and soccer. And they enjoy simulation games in which players role-play characters in a virtual reality.

Speed-and-action video games foster selective attention and spatial skills in boys and girls alike. Extensive game playing, however, is negatively related to school performance (Hastings et al., 2009; Jackson et al., 2011b; Subrahmanyam & Greenfield, 1996). And an increasing number of studies show that playing violent games, like watching violent TV, increases hostility and aggression—especially in boys, who are more avid players than girls (Anderson, 2004; Hofferth, 2010). Furthermore, video games are full of ethnic and gender stereotypes (Dietz, 1998). Much less is known about the consequences of children's experiences in computerized virtual realities. Depending on their content, some virtual-reality games may foster complex narrative skills, imagination, and prosocial behavior, whereas others may promote uncooperativeness and antisocial acts (Singer & Singer, 2005). In research conducted in Japan and the United States, young people who more often played games high in modeling of helpfulness subsequently behaved more prosocially (Gentile et al., 2009).

Compared with infrequent users, "passionate" game players tend to be anxious, withdrawn young people who use games to escape from unpleasant family and school experiences. A few become addicted: They spend several hours a day playing, constantly think about playing when they are not, and believe they play too much but cannot cut back or stop (Salguero & Morán, 2002). Excessive playing of fantasy games can blur the distinction between virtual and real life (Turkle, 1995). When such games are violent, they may contribute—along with disengaged parents, antisocial peers, and alienation from school—to commission of heinous acts by at-risk young people. Columbine High School teenage murderers Eric Harris and Dylan Klebold were obsessed with a game called *Doom,* in which players try to rack up the most kills (Subrahmanyam et al., 2001).

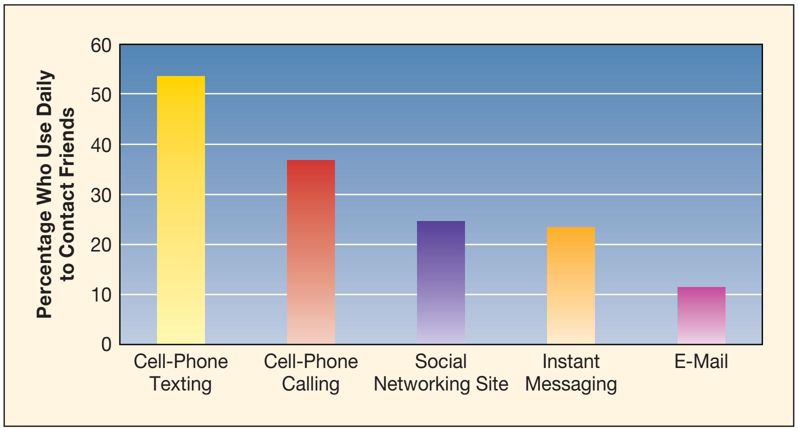


FIGURE 15.8 **Percentage of U.S. 12- to 17-year-olds who use various communication channels daily to contact friends** A nationally representative sample of 800 U.S. 12- to 17-year-olds responded to a survey about their communication strategies with friends. Cell-phone texting emerged as the preferred means of electronic communication, with over half of teenagers reporting that they used it daily. (Adapted from Lenhart et al., 2010.)

Cell Phones, the Internet, and Communication Teenagers frequently use cell phones and the Internet to communicate with friends. About 75 percent of U.S. 12- to 17-year-olds own a cell phone, a rate that has nearly doubled during the past decade. Cell-phone texting has become the preferred means of electronic interaction between teenage friends, with cell calling second, followed by social networking sites and instant messaging (see Figure 15.8). Girls use cell phones to text and call their friends considerably more often than boys (Lenhart et al., 2010). These forms of online interaction seem to support friendship closeness. In several studies, as amount of online messaging between preexisting friends increased, so did young people's perceptions of intimacy in the relationship and sense of well-being. The effect is largely due to friends' online disclosure of personal information, such as worries, secrets, and romantic feelings (Hu et al., 2004; Valkenburg & Peter, 2007a, 2007b, 2009). But about one-third of U.S. teenagers send more than 100 texts per day, half of whom send more than 200 (amounting to over 6,000 per month). The social consequences of such heavy, non–face-to-face interaction are unknown.

© MYRLEEN PEARSON/THE IMAGE WORKS

Cell-phone texting and social networking promote feelings of closeness and well-being in teenagers' relationships with friends. But for heavy users of electronic communication, social consequences are unknown.

Although mostly communicating with friends they know, adolescents are also drawn to meeting new people over the Internet. Social networking sites such as MySpace and Facebook, which are now used by nearly three-fourths of U.S. teenagers, along with blogs, message boards, and chat rooms, open up vast alternatives beyond their families, schools, and communities (Lenhart et al., 2010). Through these online ties, young people explore central adolescent issues—sexuality, challenges in parent and peer relationships, and identity issues, including attitudes and values—in contexts that grant anonymity and, therefore, may feel less threatening than similar conversations in the real world (Subrahmanyam, Smahel, & Greenfield, 2006; Valkenburg & Peter, 2011). Online interactions with strangers also offer some teenagers vital sources of support. Socially anxious youths, for example, may engage in Internet communication to relieve loneliness while practicing and improving their social skills. And teenagers suffering from depression, eating disorders, and other problems can access message boards where participants provide mutual assistance, including a sense of group belonging and acceptance (Whitlock, Powers, & Eckenrode, 2006).

But online communication also poses dangers. In unmonitored chat rooms, teenagers are likely to encounter degrading racial and ethnic slurs and sexually obscene and harassing remarks (Subrahmanyam & Greenfield, 2008). Furthermore, in a survey of a nationally representative sample of U.S. 10- to 17-year-old Internet users, 14 percent reported having formed online friendships or romances. Although some of these youths were well-adjusted, many reported high levels of conflict with parents, peer victimization, depression, and delinquency and spent extensive time on the Internet (see Figure 15.9). They also more often had been asked by online friends for face-to-face meetings and had attended those meetings—without telling their parents (Wolak, Mitchell, & Finkelhor, 2003).

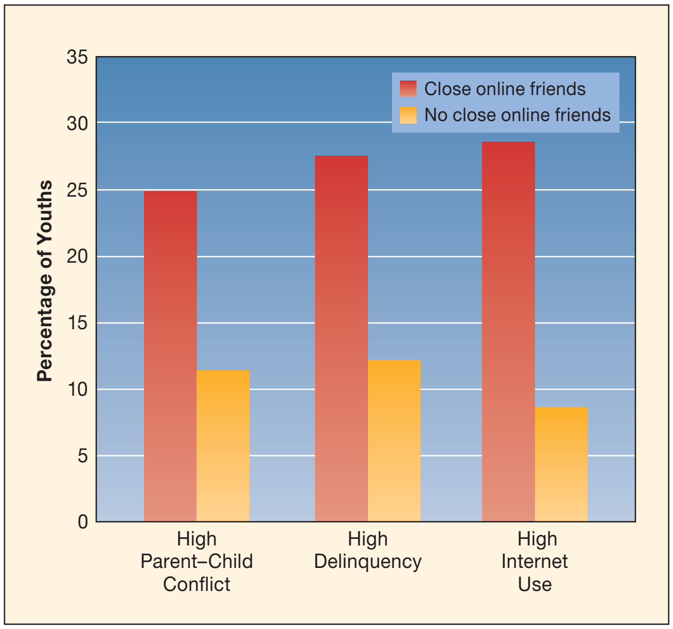

FIGURE 15.9 Association of close online friendships with parent–child conflict, delinquency, and high Internet use In this survey of a nationally representative sample of 1,500 U.S. Internet-using 10- to 17-year-olds, those who reported that they had formed close online friendships or romances were more likely to be troubled youths who spent much time on the Internet. (Adapted from Wolak, Mitchell, & Finkelhor, 2003.)

As these findings illustrate, troubled youths who use Internet communication to relieve feelings of isolation and rejection are especially vulnerable to exploitation. Adolescents who lack protective networks—family and friends with whom to discuss online encounters and appropriate and inappropriate online behaviors—may be overly trusting and may also find deceptions and harassment in Internet relationships particularly painful. Under these circumstances, Internet relationships may worsen their problems.

Regulating Media Use

The potential for TV and computer media to manipulate children's beliefs and behavior has led to strong public pressure to improve media content. In the United States, the First Amendment right to free speech has hampered efforts to regulate TV broadcasting. Instead, all programs must be rated for violent and sexual content, and all new TV sets are required to contain the V-chip (violence chip), which allows parents to block undesired material. In general, parents bear most

APPLYING WHAT WE KNOW

Regulating TV, Computer, and Cell Phone Use

STRATEGY	EXPLANATION
Limit TV viewing and computer use.	Parents should provide clear rules limiting TV and computer use by children and adolescents, and stick to them. The TV or computer should not be used as a babysitter for young children. Placing a TV or a computer in a child's bedroom substantially increases use and makes the child's activity hard to monitor.
Avoid using TV or computer time as a reward.	When TV or computer access is used as a reward or withheld as a punishment, children become increasingly attracted to it.
Encourage child-appropriate media experiences.	When children engage in TV and computer activities that are educational, prosocial, and age-appropriate, they gain in cognitive and social skills.
When possible, watch TV with children.	By raising questions about realism in TV depictions, expressing disapproval of on-screen behavior, and encouraging discussion, adults help children understand and evaluate TV content.
Link TV content to everyday learning experiences.	Parents can extend TV learning in ways that encourage children to engage actively with their surroundings. For example, a program on animals might spark a trip to the zoo, a visit to the library for books about animals, or new ways of observing and caring for the family pet.
Model good TV and computer practices.	Parents' media behavior—avoiding excessive TV and computer use and limiting exposure to harmful content—influences their children's media behavior.
Explain Internet technology and safety practices.	Children and adolescents who view the Internet as a networklike system are more likely to understand its social risks. They also benefit from instruction in appropriate online behavior and in the dangers of revealing personal information or getting together with people they have "met" online.
Monitor and limit cell phone use.	Parents should establish clear rules for cell phone use, including limits on number of call minutes and text messages and insistence that the car be a no-phone-use zone. To ensure teenagers' safety, parents should arrange with the young person for periodic checks of cell-phone contents.
Use an authoritative approach to child rearing.	Children of warm, involved parents who make reasonable demands for mature behavior are more likely to prefer media experiences with educational and prosocial content, less likely to use the TV or computer as an escape, and more likely to follow parental media rules.

responsibility for regulating their children's exposure to inappropriate media content. As with the V-chip for TV, parents can control children's Internet access by using filters or programs that monitor website visits. Yet surveys of U.S. parents and youths indicate that 20 to 30 percent of preschoolers and about half of school-age children and early adolescents experience no limits on TV or computer use at home. Some children begin visiting websites without parental supervision as early as age 4 (Rideout, Foehr, & Roberts, 2010; Rideout & Hamel, 2006; Varnhagen, 2007).

With respect to cell phone use, the overwhelming majority of U.S. parents who provide their child with a phone do so to be in touch wherever the teenager happens to be. And most adolescents appreciate the increased safety that a cell phone offers. Whereas about two-thirds of parents check the contents of their child's cell phone, less then half limit the number of minutes their child may use the phone, and less than one-third restrict the number of text messages their child may send or receive. Yet when parents limit amount of texting, adolescents less often report regretting a text message they sent and sending messages with sexual content, including images ("sexting") (Lenhart et al., 2010). Also, teenagers whose parents place limits on cell phone use are less likely to use cell phones in risky ways while driving (Madden & Lenhart, 2009). Applying What We Know above lists strategies parents can use to protect their children from undesirable TV and computer fare and cell phone use.

ASK YOURSELF

Review ■ Describe research findings on the academic and social benefits of television and computer use.

Apply ■ Thirteen-year-old Tommy spends hours each afternoon surfing the Web, instant messaging with online friends he has never met, and playing computer games. Explain why his parents should intervene.

Connect ■ Which subtypes of popular and rejected children, described on page 619, are most likely to be attracted to violent media? Explain.

Reflect ■ How much and what kinds of television viewing and computer use did you engage in as a child and adolescent? Did your parents have rules about TV and computer time, and did they enforce those rules? How do you think your home media environment influenced your development?

Schooling

- How do class and student body size and educational philosophies affect academic and social development?
- Cite factors that influence adjustment following school transitions in early childhood and in adolescence.
- Discuss the role of teacher–student interaction and grouping practices in academic achievement.
- Under what conditions is placement of students with special needs in regular classrooms successful, and how can schools increase parent involvement in education?
- How well are American young people achieving compared with their counterparts in other industrialized nations, and what problems do non-college-bound youths face in preparing for a vocation?

Unlike the informal world of peer relations, the school is a formal institution designed to transmit the knowledge and skills children need to become productive members of society. By high school graduation, children in the developed world have spent, on average, about 14,000 hours in school. As noted in earlier chapters, schools are vital forces in children's development, affecting their motivation to learn and modes of remembering, reasoning, problem solving, and social and moral understanding. How do schools exert such a powerful impact? Research looking at schools as complex social systems—class and student body size, educational philosophies, transitions from one school level to the next, teacher–student relationships, and grouping practices—provides important insights.

Class and Student Body Size

The physical plants of all schools tend to be similar: Each has classrooms, hallways, a playground, and a lunchroom. But they vary widely in number of students in each class and in the school as a whole.

Is there an optimal class size? In a large field experiment, more than 6,000 Tennessee kindergartners were randomly assigned to three class types: "small" (13 to 17 students), "regular" (22 to 25 students) with only a teacher, and regular with a teacher plus a full-time teacher's aide. These arrangements continued into third grade. Small-class students—especially ethnic minority children—scored higher in reading and math achievement each year (Mosteller, 1995). Placing teachers' aides in regular-size classes had no impact. Rather, experiencing small classes from kindergarten through third grade predicted substantially higher achievement from fourth through ninth grades, after children had returned to regular-size classes. It also predicted greater likelihood of graduating from high school, particularly for low-SES students (Finn, Gerber, & Boyd-Zaharias, 2005; Nye, Hedges, & Konstantopoulos, 2001). Many school administrators, however, argue that teacher quality is far more important than class size. In one study, small class size predicted elementary students' academic progress, even after diverse measures of teacher quality were controlled (Brühwiler & Blatchford, 2011). Once again, classes of fewer than 17 students had a particularly powerful impact.

Why is small class size beneficial? With fewer children, teachers spend less time disciplining and more time teaching and giving individual attention. Also, children who learn in smaller groups show better concentration, higher-quality class participation, and more favorable attitudes toward school (Blatchford et al., 2003, 2007). The impact of small class size on children's social behavior, however, is inconsistent and may depend on the extent to which teachers include social goals in their daily plans (NICHD Early Child Care Research Network, 2004a).

Once students reach secondary school, where they move from class to class and have access to many activities outside classroom instruction, the relevant physical context is the school as a whole. Student body size profoundly affects school life. Members of smaller schools report more social support and caring as well as greater school engagement, as indicated by student attendance, academic preparedness, and satisfaction with classes and other school experiences (Lee, 2000; Weiss, Carolan, & Baker-Smith, 2010). Furthermore, schools with 500 to 700 students or less have fewer people to ensure that clubs, sports events, and social activities will function. As a result, young people enter a greater number and variety of activities and hold more positions of responsibility and leadership. In large schools, where plenty of students are available to fill activity slots, a smaller percentage—typically an elite who compete successfully for positions—are genuinely active (Barker & Gump, 1964; Feldman & Matjasko, 2007).

Extracurricular participation focusing on the arts, community service, and vocational development promotes diverse aspects of adjustment, including improved academic performance, reduced antisocial behavior, more favorable self-esteem and initiative, and greater peer acceptance and concern for others (Fredricks & Eccles, 2005, 2006; Mahoney, 2000). Benefits extend into adult life (see also research on youth civic responsibility, Chapter 12, page 508). Young adults who were more involved in high school clubs and organizations achieved more in their occupations and engaged in more community service, after other possibly explanatory factors (including SES, IQ, and academic performance) were controlled (Obradović & Masten, 2007).

Adolescents with academic, emotional, and social problems are especially likely to profit from extracurricular pursuits that require them to take on meaningful roles and responsibilities (Mahoney & Cairns, 1997; Marsh & Kleitman, 2002). A special advantage of small schools is that potential dropouts are far more likely to join in activities, gain recognition, and remain until graduation. In large schools, reorganizations that create smaller "schools within schools" can have the same effect.

Educational Philosophies

Each teacher brings to the classroom an educational philosophy that plays a major role in children's learning. Two philosophical approaches have received most research attention. They differ in what children are taught, in the way they are believed to learn, and in how their progress is evaluated.

Traditional versus Constructivist Classrooms In a **traditional classroom,** the teacher is the sole authority for knowledge, rules, and decision making and does most of the talking. Students are relatively passive—listening, responding when called on, and completing teacher-assigned tasks. Their progress is evaluated by how well they keep pace with a uniform set of standards for their grade.

A **constructivist classroom,** in contrast, encourages students to construct their own knowledge. Although constructivist approaches vary, many are grounded in Piaget's view of children as active agents who reflect on and coordinate their own thoughts, rather than absorbing those of others. A glance inside a constructivist classroom reveals richly equipped learning centers, small groups and individuals solving self-chosen problems, and a teacher who guides and supports in response to children's needs. Students are evaluated by considering their progress in relation to their own prior development.

In the United States, the pendulum has swung back and forth between these two views. In the 1960s and early 1970s, constructivist classrooms gained in popularity. Then, as concern arose over the academic progress of children and youths, a "back to basics" movement arose, and classrooms returned to traditional instruction. This style, still prevalent today, has become increasingly pronounced as a result of the U.S. No Child Left Behind Act, signed into law in 2001 (Darling-Hammond, 2010; Ravitch, 2010). Because it places heavy pressure on teachers and school administrators to improve achievement test scores, it has narrowed the curricular focus in many schools to preparing students to take such tests (see page 343 in Chapter 8). And to devote even more time to academic instruction, many schools have cut back on recess, despite its contribution to all domains of development (refer to the Social Issues: Education box on the following page.

SOCIAL ISSUES: EDUCATION

School Recess—A Time to Play, a Time to Learn

When 7-year-old Whitney's family moved to a new city, she left a school with three daily recess periods for one with just a single 15-minute break per day, which her second-grade teacher cancelled if any child misbehaved. Whitney, who had previously enjoyed school, complained daily of headaches and an upset stomach. Her mother, Jill, thought, "My child is stressing out because she can't move all day!" After Jill and other parents successfully appealed to the school board to add a second recess period, Whitney's symptoms vanished (Rauber, 2006).

In recent years, recess—along with its rich opportunities for child-organized play and peer interaction—has diminished or disappeared in many U.S. elementary schools (Ginsburg, 2007; Pellegrini & Holmes, 2006). Under the assumption that extra time for academics will translate into achievement gains, 7 percent of U.S. schools no longer provide recess to students as young as second grade. And over half of schools that do have recess now schedule it just once a day (U.S. Department of Education, 2011b).

Yet rather than subtracting from classroom learning, recess periods boost it! Research dating back more than 100 years confirms that distributing cognitively demanding tasks over a longer time by introducing regular breaks, rather than consolidating intensive effort within one period, enhances attention and performance at all ages. Such breaks are particularly important for children. In a series of studies, school-age children were more attentive in the classroom after recess than before it—an effect that was greater for second than fourth graders (Pellegrini, Huberty, & Jones, 1995). Teacher ratings of disruptive classroom behavior also decline for children who have more than 15 minutes of recess a day (Barros, Silver, & Stein, 2009).

© ELLEN B. SENISI/THE IMAGE WORKS

School recess offers rich opportunities for child-organized games and peer interaction that promote both academic achievement and social competence.

In other research, kindergartners' and first graders' engagement in peer conversation and games during recess predicted gains in academic achievement, even after other factors that might explain the relationship (such as previous achievement) were controlled (Pellegrini, 1992; Pellegrini et al., 2002). Recall that children's social maturity contributes substantially to early academic competence. Recess is one of the few remaining contexts devoted to child-organized games that provide practice in vital social skills—cooperation, leadership, followership, and inhibition of aggression—under adult supervision rather than adult direction. As children transfer these skills to the classroom, they may participate in discussions, collaborate, follow rules, and enjoy academic pursuits more—factors that enhance motivation and achievement.

Although older elementary school children in traditional classrooms have a slight edge in achievement test scores, constructivist settings are associated with many other benefits—gains in critical thinking, greater social and moral maturity, and more positive attitudes toward school (DeVries, 2001; Rathunde & Csikszentmihalyi, 2005; Walberg, 1986). Yet despite grave concerns about its appropriateness, even preschool and kindergarten teachers have felt increased pressure to stress teacher-directed, academic training. Young children who spend much time passively sitting and doing worksheets, as opposed to being actively engaged in learning centers, display more stress behaviors (such as wiggling and rocking), have less confidence in their abilities, prefer less challenging tasks, and are less advanced in motor, academic, language, and social skills at the end of the school year (Marcon, 1999a; Stipek, 1995). Follow-ups reveal lasting effects through elementary school in poorer study habits and achievement (Burts et al., 1992; Hart et al., 1998, 2003). These outcomes are strongest for low-SES children, with whom teachers more often use an academic approach—a disturbing trend in view of its negative impact on motivation and emotional well-being (Stipek, 2004; Stipek & Byler, 1997).

In contrast, low-SES children experiencing *Montessori education*—a constructivist method devised a century ago by Italian physician Maria Montessori—reap many benefits. Features of Montessori schooling include multiage classrooms, teaching materials specially designed to promote exploration and discovery, long time periods for individual and small-group learning in child-chosen activities, and equal emphasis on academic and social development (Lillard, 2007). In an evaluation of Montessori public preschools serving mostly urban minority children in Milwaukee, researchers compared students randomly assigned to either Montessori or other classrooms (Lillard & Else-Quest, 2006). Five-year-olds who had completed two years of Montessori education outperformed controls in literacy and math skills, cognitive flexibility, false-belief understanding, concern with fairness in solving problems with peers, and cooperative play with agemates.

LOOK and LISTEN

Ask an elementary school teacher to sum up his or her educational philosophy. Is it closest to a traditional, constructivist, or social-constructivist view? Has the teacher encountered any obstacles to implementing that philosophy? Explain.

New Philosophical Directions

New approaches to education, grounded in Vygotsky's sociocultural theory, capitalize on the rich social context of the classroom to spur children's learning. In these **social-constructivist classrooms,** children participate in a wide range of challenging activities with teachers and peers, with whom they jointly construct understandings. As children *appropriate* (take for themselves) the knowledge and strategies generated from working together, they become competent, contributing members of their classroom community and advance in cognitive and social development (Bodrova & Leong, 2007; Palincsar, 2003). Vygotsky's emphasis on the social origins of higher cognitive processes has inspired the following educational themes:

- *Teachers and children as partners in learning.* A classroom rich in both teacher–child and child–child collaboration transfers culturally valued ways of thinking to children.
- *Experience with many types of symbolic communication in meaningful activities.* As children master reading, writing, and mathematics, they become aware of their culture's communication systems, reflect on their own thinking, and bring it under voluntary control.
- *Teaching adapted to each child's zone of proximal development.* Assistance that both responds to current understandings and encourages children to take the next step helps ensure that each student will make the best progress possible.

In Chapter 6, we considered two Vygotsky-inspired collaborative practices: reciprocal teaching and cooperative learning (see pages 271–272). Recognizing that collaboration requires a supportive context to be most effective, another Vygotsky-based innovation makes it a schoolwide value. Classrooms become **communities of learners** where teachers guide the overall process of learning but no other distinction is made between adult and child contributors: All participate in joint endeavors and have the authority to define and resolve problems. This approach is based on the assumption that different people have different expertises that can benefit the community and that students, too, may become experts (Sullivan & Glanz, 2006). Classroom activities are often long-term projects addressing complex, real-world problems. In working toward project goals, children and teachers draw on one another's expertises and those of others within and outside the school.

In one classroom, students studied animal–habitat relationships in order to design an animal of the future, suited to environmental changes. The class formed small research groups, each of which selected a subtopic—for example, defense against predators, protection from the elements, reproduction, or food getting. Each group member assumed responsibility for part of the subtopic, consulting diverse experts and preparing teaching materials. Then group members taught one another, assembled their contributions, and brought them to the community as a whole so the knowledge gathered could be used to solve the problem (Brown, 1997; Stone, 2005). The result was a multifaceted understanding of the topic that would have been too difficult and time-consuming for any learner to accomplish alone.

© ALISTAIR BERG/GETTY IMAGES/DIGITAL VISION

A teacher and students form a community of learners to plan, plant, and track the growth of a vegetable garden. During this complex, long-term project, participating adults and children may all become experts, sharing knowledge with one another.

School Transitions

Besides size and educational philosophy, an additional structural feature of schooling contributes to student achievement and adjustment: the timing of transitions from one school level to the next. Entering kindergarten is a major milestone. Children must accommodate to new physical settings, adult authorities, daily schedules, peer companions, and academic challenges.

Early Adjustment to School In longitudinal research extending over the school year, the ease with which kindergartners made new friends, were accepted by their classmates, and related to their teachers predicted cooperative participation in classroom activities and self-directed completion of learning tasks. These behaviors, in turn, were related to gains in achievement during kindergarten (Ladd, Birch, & Buhs, 1999; Ladd, Buhs, & Seid, 2000). Furthermore, children with friendly, prosocial styles more easily made new friends, gained peer acceptance, and formed a warm bond with their teacher. In contrast, those with weak emotional self-regulation skills and argumentative, aggressive, or peer-avoidant styles established poor-quality relationships and made few friends (Birch & Ladd, 1998).

The capacity to form positive peer and teacher relationships enables kindergartners to integrate themselves into classroom environments in ways that foster both academic and social competence. In a follow-up of more than 900 4-year-olds, children of average intelligence but with above-average social skills fared better in academic achievement in first grade than children of equal mental ability who were socially below average (Konold & Pianta, 2005). Because social maturity in early childhood contributes to later academic performance, a growing number of experts propose that readiness for kindergarten be assessed in terms of not just academic skills but also social skills, including capacity to form supportive bonds with teachers and peers, to participate actively and positively in interactions with classmates, and to behave prosocially (Ladd, Herald, & Kochel, 2006; Thompson & Raikes, 2007).

Preschool interventions, too, should attend to these vital social prerequisites. Warm, responsive teacher–child interaction is vital, especially for temperamentally shy, impulsive, and emotionally negative children, who are at high risk for social difficulties (McClelland et al., 2007). In studies involving several thousand 4-year-olds in public preschools in six states, teacher sensitivity and emotional support were especially potent predictors of children's social competence during preschool and in a follow-up after kindergarten entry (Curby et al., 2009; Mashburn et al., 2008).

School Transitions in Adolescence Early adolescence is another important period of school transition: Students typically move from an intimate, self-contained elementary school classroom to a much larger, impersonal secondary school where they must shift between classes. With each school change—from elementary to middle or junior high and then to high school—adolescents' grades decline. The drop is partly due to tighter academic standards. At the same time, the transition to secondary school often brings less personal attention, more whole-class instruction, and less chance to participate in classroom decision making (Seidman, Aber, & French, 2004).

In view of these changes, it is not surprising that students rate their middle or junior-high school learning experiences less favorably than their elementary school experiences (Wigfield & Eccles, 1994). They also report that their teachers care less about them, are less friendly, grade less fairly, and stress competition more. Consequently, many young people feel less academically competent, and their liking for school and motivation decline (Barber & Olsen, 2004; Gutman & Midgley, 2000; Otis, Grouzet, & Pelletier, 2005).

Inevitably, students must readjust their feelings of self-confidence and self-worth as they encounter revised academic expectations and a more complex social world. In several studies that followed students across the middle- and high-school transitions, grade point average declined and feelings of anonymity increased after each school change. Girls fared less well than boys. On entering middle school, girls' self-esteem dropped sharply, perhaps because the transition tended to coincide with other life changes: the onset of puberty and dating (Simmons & Blythe, 1987). And after starting high school, girls felt lonelier and more anxious than boys, and—although they were doing better academically—their grades declined more rapidly (Benner & Graham, 2009; Russell, Elder, & Conger, 1997).

Adolescents facing added strains at either transition—family disruption, poverty, low parental involvement, high parental conflict, or learned helplessness on academic tasks—are at greatest risk for self-esteem and academic difficulties

© DWIGHT CENDROWSKI, WWW.CENDROWSKI.COM

This seventh grader hurries at his locker so he won't be late for class at his new middle school. Moving from a small, self-contained elementary school classroom to a large, impersonal secondary school is stressful for adolescents.

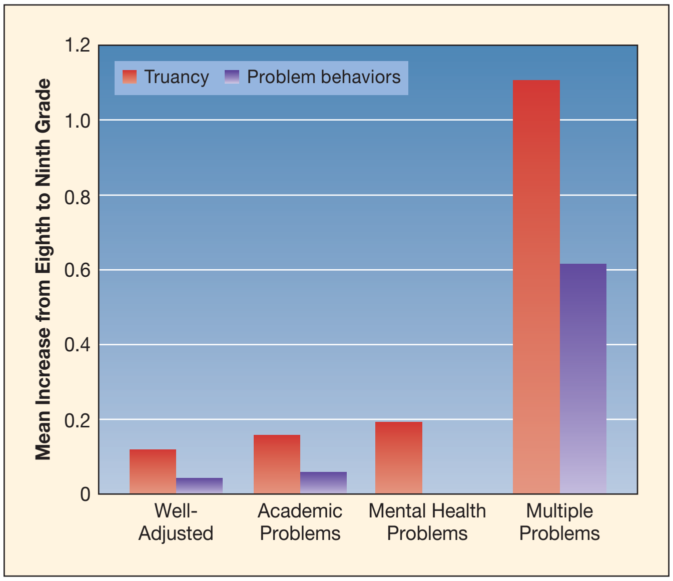

FIGURE 15.10 Increase in truancy and out-of-school problem behaviors across the transition to high school in four groups of students Well-adjusted students, students with only academic problems, and students with only mental health problems showed little change. (Good students with mental health problems actually declined in problem behaviors, so no purple bar is shown for them.) In contrast, multiple-problem students—with both academic and mental health difficulties—increased sharply in truancy and problem behaviors after changing schools from eighth to ninth grade. (Adapted from Roeser, Eccles, & Freedman-Doan, 1999.)

(de Bruyn, 2005; Rudolph et al., 2001; Seidman et al., 2003). Furthermore, the high school transition is particularly challenging for African-American and Hispanic students who move to a new school with substantially fewer same-ethnicity peers (Benner & Graham, 2009). Under these conditions, minority adolescents report decreased feelings of belonging and school liking, and they show steeper declines in grades.

Distressed youths whose school performance either remains low or drops sharply after school transition often show a persisting pattern of poor self-esteem, motivation, and achievement. In another study, researchers compared "multiple-problem" youths (those with both academic and mental health problems), youths with difficulties in just one area (either academic or mental health), and well-adjusted youths (those doing well in both areas) across the transition to high school. Although all groups declined in grade point average, well-adjusted students continued to get high marks and multiple-problem youths low marks, with the others falling in between. And as Figure 15.10 shows, the multiple-problem youths showed a far greater rise in truancy and out-of-school problem behaviors, such as doing something dangerous for the thrill of it, damaging public property, or getting drunk (Roeser, Eccles, & Freedman-Doan, 1999). For some, school transition initiates a downward spiral in academic performance and school involvement that leads to dropping out.

Helping Adolescents Adjust to School Transitions As these findings reveal, school transitions often lead to environmental changes that fit poorly with adolescents' developmental needs (Eccles & Roeser, 2009). They disrupt close relationships with teachers at a time when adolescents need adult support. They emphasize competition during a period of heightened self-focusing. They reduce decision making and choice as the desire for autonomy is increasing. And they interfere with peer networks as young people become more concerned with peer acceptance.

Support from parents, teachers, and peers can ease these strains. Parental involvement, monitoring, autonomy granting, and emphasis on mastery rather than merely good grades are associated with better adjustment (Grolnick et al., 2000; Gutman, 2006). Adolescents with close friends are more likely to sustain these friendships across the transition, which increases social integration and academic motivation in the new school (Aikens, Bierman, & Parker, 2005). Forming smaller units within large schools promotes closer relations with both teachers and peers and greater extracurricular involvement (Seidman, Aber, & French, 2004). And a "critical mass" of same-ethnicity peers—according to one suggestion, at least 15 percent of the student body—helps teenagers feel socially accepted and reduces fear of out-group hostility (National Research Council, 2007).

Other, less extensive changes are also effective. In the first year after a school transition, homerooms can be provided in which teachers offer academic and personal counseling and work closely with parents to promote favorable adjustment. Assigning students to classes with several familiar peers or a constant group of new peers strengthens emotional security and social support. In schools that took these steps, students were less likely to decline in academic performance or display other adjustment problems (Felner et al., 2002).

Finally, teenagers' perceptions of the sensitivity and flexibility of their school learning environments contribute substantially to successful school transitions. When schools minimize competition and differential treatment based on ability, middle school students are less likely to feel angry and depressed, to be truant, or to show declines in academic values, self-esteem, and achievement (Roeser, Eccles, & Sameroff, 2000). School rules that strike young people as fair rather than punitive also foster satisfaction with school life.

LOOK and LISTEN

Ask several secondary school students to describe their experiences after school transition. What supports for easing the stress of transition did their teachers and school provide?

Teacher–Student Interaction

The classroom is a complex social system in which teachers engage in as many as 1,000 exchanges with students each day (Jackson, 1968). Extensive research exists on teacher–student interaction, most focusing on its significance for academic achievement.

Elementary and secondary school students describe good teachers as caring, helpful, and stimulating—behaviors associated with gains in motivation, achievement, and favorable peer relations (Hughes & Kwok, 2006, 2007; Hughes, Zhang, & Hill, 2006; O'Connor & McCartney, 2007). But too many U.S. teachers emphasize repetitive drill over higher-level thinking, such as grappling with ideas and applying knowledge to new situations (Sacks, 2005). In a longitudinal investigation of a large sample of middle school students, those in more stimulating, academically demanding classrooms showed better attendance and larger gains in math achievement over the following two years (Phillips, 1997).

As we have seen, teachers do not interact in the same way with all children. Well-behaved, high-achieving students typically get more encouragement and praise, whereas unruly students have more conflicts with teachers and receive more criticism from them (Henricsson & Rydell, 2004). Caring teacher–student relationships have an especially strong impact on the achievement and social behavior of low-SES minority students and other children at risk for learning difficulties (Baker, 2006; Crosno, Kirkpatrick, & Elder, 2004). But overall, higher-SES students—who tend to be higher achieving and to have fewer learning and behavior problems—have more sensitive and supportive relationships with teachers (Jerome, Hamre, & Pianta, 2009; Pianta, Hamre, & Stuhlman, 2003).

Unfortunately, once teachers' attitudes toward students are established, they can become more extreme than is warranted by students' behavior. Of special concern are **educational self-fulfilling prophecies:** Children may adopt teachers' positive or negative views and start to live up to them.[1] As early as first grade, teachers' beliefs in children's ability to learn predict students' year-end achievement progress after controlling for students' beginning-of-year performance. This effect is particularly strong when teachers emphasize competition and publicly compare children, regularly favoring the best students (Kuklinski & Weinstein, 2001; Weinstein, 2002).

Teacher expectations have a greater impact on low-achieving than high-achieving students (Madon, Jussim, & Eccles, 1997). When a teacher is critical, high achievers can fall back on their history of success. Low-achieving students' sensitivity to self-fulfilling prophecies can be beneficial when teachers believe in them. But biased teacher judgments are usually slanted in a negative direction. In one study, African-American and Hispanic elementary school students taught by high-bias teachers (who expected them to do poorly) showed substantially lower end-of-year achievement than their counterparts taught by low-bias teachers (McKown & Weinstein, 2008). And in a Dutch investigation, teachers' subtle prejudices against Turks and Moroccans were associated with a larger achievement gap between Dutch-origin and ethnic minority first through sixth graders (van den Bergh et al., 2010). Recall our discussion of *stereotype threat* in Chapter 8. A child in the position of confirming a negative stereotype may respond with anxiety and reduced motivation, amplifying a negative self-fulfilling prophecy.

Grouping Practices

Many schools group students by ability or track them into classes in which students of similar achievement levels are taught together. The goal is to reduce the need for individual teachers to meet a wide range of academic needs.

Grouping in Elementary School *Homogeneous* groups or classes can be a potent source of self-fulfilling prophecies. Low-group students—who as early as first grade are disproportionately low-SES, minority, and male—get more drill on basic facts and skills, engage

---

[1] Most research on self-fulfilling prophecies focuses on teacher–student relationships, but the effect can occur in other social contexts, such as parent–child and peer relationships.

These first through third graders collaborate on a variety of tasks. Compared to children in single-grade classrooms, those in multigrade classrooms are usually advantaged in academic achievement, self-esteem, and attitudes toward school.

in less discussion, and progress at a slower pace. Gradually, they decline in academic self-esteem and motivation and fall further behind in achievement (Lleras & Rangel, 2009; Trautwein et al., 2006; Worthy, Hungerford-Kresser, & Hampton, 2009). Unfortunately, widespread SES and ethnic segregation in U.S. schools consigns large numbers of low-SES minority students to a form of schoolwide, deleterious homogeneous grouping. Refer to the Social Issues: Education box on the following page to find out how magnet schools foster heterogeneous learning contexts, thereby reducing achievement disparities between SES and ethnic minority groups.

Another way schools can increase the *heterogeneity* of student groups is to combine two or three adjacent grades. In *multigrade classrooms,* academic achievement, self-esteem, and attitudes toward school are usually more favorable than in the single-grade arrangement, perhaps because multigrade classrooms often decrease competition and increase harmony (Lloyd, 1999; Ong, Allison, & Haladyna, 2000). The opportunity that mixed-grade grouping affords for peer tutoring may also contribute to its favorable outcomes. When older or more expert students teach younger or less expert students, both tutors and tutees benefit in achievement and self-esteem, with stronger effects for low-SES minority students and students in the early elementary school grades (Ginsburg-Block, Rohrbeck, & Fantuzzo, 2006; Renninger, 1998).

However, small, heterogeneous groups of students working together often engage in poorer-quality interaction (less accurate explanations and answers) than homogeneous groups of above-average students (Webb, Nemer, & Chizhik, 1998). In Chapter 6, we noted that for collaboration between heterogeneous peers to succeed, children often need extensive guidance (see page 271). When teachers provide this assistance, heterogeneous classrooms are desirable into middle or junior high school, resulting in clearer explanations, greater enjoyment of learning, and achievement gains across a wide range of school subjects (Gillies, 2003; Terwel et al., 2001; Webb et al., 2008).

© BOB DAEMMRICH/PHOTOEDIT

In U.S. secondary schools, low-SES minority students tend to be placed in lower-level courses with less stimulating teaching. The resulting boredom and disengagement are associated with slower academic progress and increased risk of dropping out.

Grouping in High School

By high school, some homogeneous grouping is unavoidable because certain aspects of education must dovetail with the young person's educational and vocational plans. In the United States, high school students are counseled into college preparatory, vocational, or general education tracks. Unfortunately, low-SES minority students are assigned in large numbers to noncollege tracks, perpetuating educational inequalities of earlier years.

Longitudinal research following thousands of U.S. students from eighth to twelfth grade reveals that assignment to a college track accelerates academic progress, whereas assignment to a vocational or general education track decelerates it (Hallinan & Kubitschek, 1999). Even in secondary schools without an overarching tracking program, low-SES minority students tend to be assigned to lower course levels in most or all academic subjects, resulting in *de facto* (unofficial) *tracking* (Lucas & Behrends, 2002).

Breaking out of a low academic track is difficult. Track or course enrollment is generally based on past performance, which is limited by placement history. Interviews with African-American students revealed that many thought their previous performance did not reflect their ability. Yet teachers and counselors, overburdened with other responsibilities, had little time to reconsider individual cases (Ogbu, 2003). And compared to students in higher tracks, students in low tracks exert substantially less effort—a difference due in part to less stimulating classroom experiences (Worthy, Hungerford-Kresser, & Hampton, 2009).

SOCIAL ISSUES: EDUCATION

Magnet Schools: Equal Access to High-Quality Education

Each school-day morning, Emma leaves her affluent suburban neighborhood, riding a school bus 20 miles to a magnet school in an impoverished, mostly Hispanic inner-city community. In her sixth-grade class, she settles into a science project with her friend, Maricela, who lives in the local neighborhood. For the first hour of the day, the girls use a thermometer, ice water, and a stopwatch to determine which of several materials is the best insulator, recording and graphing their data. Throughout the school, which specializes in innovative math and science teaching, students diverse in SES and ethnicity learn side-by-side.

Despite the 1954 U.S. Supreme Court *Brown v. Board of Education* decision ordering schools to desegregate, school integration has receded since the late 1980s, as federal courts canceled their integration orders and returned this authority to states and cities. Today, the racial divide in American education is deepening. African-American children are just as likely to attend a school that serves a mostly black population as they were in the 1960s; Hispanic children are even more segregated. And when minority students attend ethnically mixed schools, they typically do so with other minorities (Frankenburg & Orfield, 2007).

U.S. schools in inner-city, low-income neighborhoods are vastly disadvantaged in funding and therefore in educational opportunities, largely because public education is primarily supported by local property taxes. Federal and state grants-in-aid are not sufficient to close this funding gap between rich and poor districts (Darling-Hammond, 2010). Consequently, in inner-city segregated neighborhoods, dilapidated school buildings; inexperienced teachers; outdated, poor-quality educational resources; and school cultures that fail to encourage strong teaching are widespread (Kozol, 2005). The negative impact on student achievement is severe.

A promising solution is the establishment of magnet schools. In addition to the usual curriculum, they emphasize a specific area of interest—such as performing arts, math and science, or technology. Families outside the school neighborhood are attracted to magnet schools (hence the name) by their rich academic offerings. Often magnets are located in low-income, minority areas, where they serve the neighborhood student population. Other students, who apply and are admitted by lottery, are bussed in—many from well-to-do city and suburban neighborhoods. In another model, all students—including those in the surrounding neighborhood—must apply. In either case, magnet schools are voluntarily desegregated.

Research confirms that less segregated education enhances minority student achievement (Linn & Welner, 2007). Is this so for magnet schools? A Connecticut study comparing seventh to tenth graders enrolled in magnet schools with those whose lottery numbers were not drawn and who therefore attended other city schools confirmed that the magnets served a far more diverse student population. Although magnet-school enrollees and nonadmitted applicants were similar in ethnicity, SES, and prior academic achievement, magnet students showed greater gains in reading and math achievement over a two-year period—outcomes especially pronounced for low-SES, ethnic minority students (Bifulco, Cobb, & Bell, 2009).

By high school, the higher-achieving peer environments of ethnically diverse schools encourage more students to pursue higher education (Frankenburg & Orfield, 2007). And as we saw in Chapter 11, a diverse student body also provides opportunities for social learning that can combat racial prejudice. In sum, magnet schools are a promising approach to overcoming the negative forces of SES and ethnic isolation in American schools.

© ELLEN B. SENISI/THE IMAGE WORKS

Third graders at a fine arts magnet school jointly create a painting. The ethnically diverse learning environments of many magnet schools enhance academic achievement, especially among low-SES minority students.

High school students are separated into academic and vocational tracks in virtually all industrialized nations. In China, Japan, and most Western European countries, high school track placement is determined by a national exam, which usually establishes the young person's future possibilities. In the United States, students who are not assigned to a college preparatory track or who do poorly in high school can still attend college. Ultimately, however, many young people do not benefit from the more open U.S. system. By adolescence, SES differences in quality of education and academic achievement are greater in the United States than in most other industrialized countries (Marks, Cresswell, & Ainley, 2006). And the United States has a higher percentage of young people—about 8 percent—who view themselves as educational failures, drop out of school, and by their mid-twenties still have not completed a high school program (U.S. Department of Education, 2011b).

Teaching Students with Special Needs

We have seen that effective teachers flexibly adjust their teaching strategies to accommodate students with a wide range of characteristics. But these adjustments are especially challenging when children have learning difficulties.

Children with Learning Difficulties

U.S. legislation mandates that schools place children who require special supports for learning in the "least restrictive" (as close to normal as possible) environments that meet their educational needs. In **inclusive classrooms,** students with learning difficulties learn alongside typical students in the regular educational setting for part or all of the school day—a practice designed to prepare them for participation in society and to combat prejudices against individuals with disabilities that lead to social exclusion (Kugelmass & Ainscow, 2004). Largely as the result of parental pressures, an increasing number of students experience *full inclusion*—full-time placement in regular classrooms.

Some students in inclusive classrooms have *mild mental retardation:* Their IQs fall between 55 and 70, and they also show problems in adaptive behavior, or skills of everyday living (American Psychiatric Association, 2000). But the largest number—5 to 10 percent of school-age children—have **learning disabilities,** great difficulty with one or more aspects of learning, usually reading. As a result, their achievement is considerably behind what would be expected on the basis of their IQ. Sometimes, deficits express themselves in other ways—for example, as severe inattention, which depresses both IQ and achievement test scores (see page 290 in Chapter 7). The problems of students with learning disabilities cannot be traced to any obvious physical or emotional difficulty or to environmental disadvantage. Instead, deficits in brain functioning are involved (Waber, 2010). Some learning disabilities run in families, and in certain cases, specific genes have been identified that contribute to the problem (Miller, Sanchez, & Hynd, 2003; Raskind et al., 2005). In many instances, the cause is unknown.

© ELLEN B. SENISI PHOTOGRAPHY

In an inclusive second-grade classroom, a special-needs child listens to his classmate read a story. The child is likely to do well if he receives support from a special education teacher and if his classroom teacher minimizes comparisons and promotes cooperative learning.

How Effective Are Inclusive Classrooms?

Although some students benefit academically from inclusion, many do not. Achievement gains depend on both the severity of the disability and the support services available (Downing, 2010). Furthermore, children with disabilities are often rejected by regular-classroom peers. Students with mental retardation are overwhelmed by the social skills of their classmates; they cannot interact adeptly in a conversation or game. And the processing deficits of some students with learning disabilities lead to problems in social awareness and responsiveness (Kelly & Norwich, 2004; Lohrmann & Bambara, 2006).

Does this mean that children with special needs cannot be served in regular classrooms? Not necessarily. Often these children do best when they receive instruction in a resource room for part of the day and in the regular classroom for the remainder—an arrangement that the majority of school-age children with learning disabilities say they prefer (Vaughn & Klingner, 1998; Weiner & Tardif, 2004). In the resource room, a special education teacher works with students on an individual and small-group basis. Then, depending on their progress, children join regular classmates for different subjects and amounts of time.

Special steps must be taken to promote positive peer relations in inclusive classrooms. Cooperative learning and peer-tutoring experiences in which teachers guide children with learning difficulties and their classmates in working together lead to friendly interaction, improved peer acceptance, and achievement gains (Fuchs et al., 2002a, 2002b). Teachers can also prepare their class for the arrival of a student with special needs. Under these conditions, inclusion may foster emotional sensitivity and prosocial behavior among regular classmates.

Parent–School Partnerships

Regardless of students' age, abilities, gender, SES, or ethnicity, parent involvement in education—keeping tabs on the child's progress, communicating often with teachers, and ensuring that the child is enrolled in challenging, well-taught classes—promotes academic motivation and achievement (Hill & Taylor, 2004; Hill & Tyson, 2009; Jeynes, 2005). Parents who are in frequent contact with the school send a message to their child about the value of education, model constructive solutions to academic problems, and (as children get older) promote wise educational decisions. Involved parents also learn from other parents about which classes and teachers are the best and how to handle difficult situations. And teachers and parents are more likely to give students consistent messages about academic and behavioral expectations.

Families living in low-income, high-risk neighborhoods often feel disconnected from their children's schools, and they face daily stresses that reduce their energy for school involvement (Walker, Shenker, & Hoover-Dempsey, 2010; Warren et al., 2009). Yet stronger home–school links can relieve some of this stress. Schools can build parent–school partnerships by strengthening personal relationships between teachers and parents, showing parents how to support their child's education at home, building bridges between minority home cultures and the culture of the school, enlisting the help of neighborhood organizations with deep roots in the lives of families, and including parents in school governance so they remain invested in school goals.

How Well-Educated Are American Young People?

Our discussion has focused largely on how teachers can support the education of children and adolescents. Yet we have also seen in this and previous chapters that many factors—both within and outside schools—affect children's learning. Societal values, school resources, quality of teaching, and parental encouragement all play important roles. These multiple influences are especially apparent when schooling is examined in cross-cultural perspective.

Cross-National Research on Academic Achievement

In international studies of reading, mathematics, and science achievement, young people in China, Korea, and Japan are consistently top performers. Among Western nations, Australia, Canada, Finland, the Netherlands, and Switzerland are also in the top tier. But U.S. students typically perform at or below the international averages (see Figure 15.11) (Programme for International Student Assessment, 2009).

	Country	Average Math Achievement Score
High-Performing Nations	China (Shanghai)	600
	Singapore	562
	China (Hong Kong)	555
	Korea	546
	Taiwan	543
	Finland	541
	Switzerland	534
	Japan	529
	Canada	527
	Netherlands	526
	China (Macao)	525
	New Zealand	519
	Belgium	515
	Australia	514
	Germany	513
Intermediate-Performing Nations	Iceland	507
	Denmark	503
	Norway	498
	France	497
International Average = 496	Austria	496
	Poland	495
	Sweden	494
	Czech Republic	493
	United Kingdom	492
	Hungary	490
	Luxembourg	489
	United States	**487**
	Ireland	487
	Portugal	487
	Italy	483
	Spain	483
Low-Performing Nations	Russian Federation	468

FIGURE 15.11 **Average mathematics scores of 15-year-olds by country.** The Programme for International Student Assessment assesses achievement in many nations around the world. In its most recent comparison of countries' performance, the United States performed below the international average in math; in reading and science, its performance was about average. (Adapted from Programme for International Student Assessment, 2009.)

Why do U.S. students fall behind in academic accomplishments? According to international comparisons, instruction in the United States is less challenging, more focused on absorbing facts, and less focused on high-level reasoning and critical thinking than in other countries. A growing number of experts believe that the U.S. No Child Left Behind Act has contributed to these trends because it mandates severe sanctions for schools whose students do not meet targeted goals on achievement tests—initially, student transfers to higher-performing schools, and ultimately, staff firing, closure, state takeover, or other restructuring (Darling-Hammond, 2010;

Noguera, 2010; Ravitch, 2010). Furthermore, compared with top-achieving nations, the United States is far less equitable in the quality of education it provides to its low-income and ethnic minority students. And U.S. teachers vary much more in training, salaries, and teaching conditions.

Finland is a case in point. In the 1980s, it abandoned a national testing system used to ability-group students and replaced it with curricula, teaching practices, and assessments aimed at cultivating initiative, problem solving, and creativity—vital abilities needed for success in the twenty-first century. Finnish teachers are highly trained: They must complete several years of graduate-level education at government expense (Sahlberg, 2010). And the Finnish education is grounded in equal opportunity for all—a policy that has nearly eliminated SES variations in achievement, despite an influx of immigrant students from low-income families into Finnish schools over the past decade.

© STUART CONWAY

These Finnish students benefit from a national education system designed to cultivate initiative, problem solving, and creativity. Grounded in equal opportunity for all, Finnish education has nearly eliminated SES variations in achievement.

In-depth research on learning environments in Asian nations, such as Japan, Korea, and Taiwan, also highlights social forces that foster strong student learning. Among these is cultural valuing of effort. Whereas American parents and teachers tend to regard native ability as the key to academic success, Japanese, Korean, and Taiwanese parents and teachers believe that all children can succeed academically as long as they try hard. Asian parents devote many more hours to helping their children with homework (Stevenson, Lee, & Mu, 2000). And Asian children, influenced by collectivist values, typically view striving to do well in school as a moral obligation—part of their responsibility to family and community (Hau & Ho, 2010).

As in Finland, students in Japan, Korea, and Taiwan receive the same nationally mandated, high-quality curriculum, delivered by teachers who are well-prepared, highly respected in their society, and far better paid than U.S. teachers (Kang & Hong, 2008; U.S. Department of Education, 2011a). Academic lessons are particularly well-organized and presented in ways that capture children's attention and encourage high-level thinking (Grow-Maienza, Hahn, & Joo, 2001). And Japanese teachers are three times as likely as U.S. teachers to work outside class with students who need extra help (Woodward & Ono, 2004).

The Finnish and Asian examples underscore the need for American families, schools, and the larger society to work together to upgrade education. Over the past decade, U.S. international rankings in reading, math, and science achievement have declined. And following several decades of gains, from 1999 on the U.S. National Assessment of Educational Progress—in which challenging achievement tests are given to nationally representative samples of 9-, 13-, and 17-year-olds—showed only slight gains in reading and no improvement in math (U.S. Department of Education, 2008). These disappointing achievement outcomes underscore the need for a "broader, bolder approach to U.S. education." Recommended strategies, verified by research, include:

- providing intellectually challenging, relevant instruction with real-world applications
- strengthening teacher education
- supporting parents in creating stimulating home learning environments, monitoring their children's academic progress, and communicating often with teachers
- investing in high-quality preschool education, so every child arrives at school ready to learn
- vigorously pursuing school improvements that reduce the large inequities in quality of education between SES and ethnic groups (Economic Policy Institute, 2010).

Effective educational change must take into account students' life backgrounds and future goals. As we will see next, besides improving academic instruction, special efforts are needed in vocational education to help non-college-bound youths prepare for productive work roles.

Vocational Preparation of Non-College-Bound Adolescents

Approximately one-third of U.S. young people graduate from high school without plans to go to college. Although they are more likely to find employment than those who drop out, changes in the labor market over the past several decades—labor-saving technologies, outsourcing of U.S. jobs to other countries, and a minimum wage that has not kept up with inflation—have drastically reduced viable work opportunities for high school graduates (Danziger & Ratner, 2010). About 20 percent of recent U.S. high school graduates who do not continue their education are unemployed (U.S. Department of Education, 2011b). When they do find work, most hold low-paid, unskilled jobs. In addition, they have few alternatives for vocational counseling and job placement as they transition from school to work.

American employers regard recent high school graduates as poorly prepared for skilled business and industrial occupations and manual trades. And there is some truth to this impression. In high school, about one-fourth of U.S. adolescents are employed—a greater percentage than in other developed countries. But most are middle-SES students in pursuit of spending money rather than vocational exploration and training. Low-income teenagers who need to contribute to family income or to support themselves find it much harder to get jobs (U.S. Census Bureau, 2011b).

Adolescents typically hold jobs that involve low-level, repetitive tasks and provide little contact with adult supervisors. A heavy commitment to such jobs is harmful. The more hours students work, the poorer their school attendance, the lower their grades, the less likely they are to participate in extracurricular activities, and the more likely they are to drop out (Marsh & Kleitman, 2005). Students who spend many hours at such jobs also tend to feel more distant from their parents and report more drug and alcohol use and delinquent acts (Kouvonen & Kivivuori, 2001; Staff & Uggen, 2003).

© DAVID YOUNG-WOLFF/PHOTO EDIT

Teenagers' employment opportunities are generally limited to menial, repetitive tasks. Students with a heavy time commitment to such jobs are less likely to participate in extracurricular activities and more likely to drop out of school.

In contrast, participation in work–study programs or other jobs that provide academic and vocational learning opportunities is related to positive school and work attitudes, achievement, and reduced delinquency (Hamilton & Hamilton, 2000; Staff & Uggen, 2003). Yet high-quality vocational preparation for non-college-bound U.S. adolescents is scarce. Unlike some European nations, the United States has no widespread training systems to prepare youths for skilled business and industrial occupations and manual trades. Although U.S. federal and state governments support some job-training programs, most are too brief to make a difference and serve only a small minority of young people who need assistance.

In Germany, adolescents who do not go to a Gymnasium (college-preparatory high school) have access to one of the world's most successful work–study apprenticeship systems for entering business and industry. About two-thirds of German youths participate. After completing full-time schooling at age 15 or 16, they spend the remaining two years of compulsory education in the Berufsschule, combining part-time vocational courses with an apprenticeship that is jointly planned by educators and employers. Students train in work settings for more than 350 blue- and white-collar occupations (Deissinger, 2007). Apprentices who complete the program and pass a qualifying examination are certified as skilled workers and earn union-set wages. Businesses provide financial support because they know that the program guarantees a competent, dedicated work force (Heinz, 1999; Kerckhoff, 2002). Many apprentices are hired into well-paid jobs by the firms that train them.

AP IMAGES/CAROLYN KASTER

At a technical high school in Pennsylvania, a baking and pastry student puts the finishing touches on a cake. High-quality vocational education, integrated with academic instruction, motivates students at risk for dropping out to stay in school.

The success of the German system—and of similar systems in Austria, Denmark, Switzerland, and several Eastern European countries—suggests that a national apprenticeship program would improve the transition from high school to work for U.S. non-college-bound young people. The many benefits of bringing together the worlds of schooling and work include helping non-college-bound young people establish productive lives right after graduation, motivating at-risk youths to stay in school, and contributing to the nation's economic growth. Nevertheless, implementing an apprenticeship system poses major challenges: overcoming the reluctance of employers to assume part of the responsibility for vocational training, ensuring cooperation between schools and businesses, and preventing low-SES youths from being concentrated in the lowest-skilled apprenticeship placements or from being unable to find any placement, an obstacle that Germany itself has not yet fully overcome (Lang, 2010).

Currently, small-scale school-to-work projects in the United States are attempting to solve these problems and build bridges between learning and working. Young people who are well-prepared for an economically and personally satisfying work life are much more likely to become productive citizens, devoted family members, and contented adults. The support of families, schools, businesses, communities, and society as a whole can contribute greatly to a positive outcome.

ASK YOURSELF

Review ■ List educational practices that promote positive attitudes toward school, academic motivation, and achievement, and explain why each is effective.

Connect ■ What common factors contribute to the high academic achievement of students in Asian nations and to the academic success of immigrant youths, discussed on page 53 in Chapter 2?

Apply ■ Ray is convinced that his 5-year-old son Trip would learn more in school if only Trip's kindergarten would provide more teacher-directed lessons and worksheets and reduce the time devoted to learning-center activities. Is Ray correct? Explain.

Reflect ■ Describe your experiences in making the transition to middle or junior high school and then to high school. What made these transitions stressful? What helped you adjust?

SUMMARY

Peer Relations (p. 607)

Trace the development of peer sociability from infancy into adolescence, and discuss various influences on peer sociability.

- Peer sociability begins in infancy with isolated social acts, followed by coordinated exchanges in the second year. During the preschool years, play moves from **nonsocial activity** to **parallel play** and then to **associative** and **cooperative play**. Sociodramatic play becomes especially frequent, supporting cognitive, emotional, and social development.
- In middle childhood, improved perspective taking permits peer interaction to become more prosocial and cooperative and to transition to rule-oriented games. **Rough-and-tumble play**—important in our evolutionary past for developing fighting skill and establishing **dominance hierarchies**—also becomes common, especially among boys.
- Parents influence children's social competence both directly, by providing guidance and opportunities for peer contact, and indirectly, through their child-rearing practices.

© LAURA DWIGHT PHOTOGRAPHY

- Same-age peers engage in more intense and harmonious exchanges, but mixed-age interaction allows children to acquire new competencies from older companions.
- In collectivist societies, large-group, imitative play is common. Western-style sociodramatic play is particularly important for social development in societies where child and adult worlds are distinct.

Describe developing concepts and characteristics of friendships in childhood and adolescence, as well as implications of friendship for psychological adjustment.

- For preschool and young school-age children, **friendship** is a concrete relationship based on shared activities. During middle childhood, children form friendships based on mutual trust. Teenagers' friendships are based on intimacy, mutual understanding, and loyalty.
- With age, friendships become more selective, stable, and prosocial, providing contexts in which children learn to tolerate criticism and resolve disputes.

- Friends tend to be alike in age, sex, ethnicity, and SES—and, from middle childhood on, in personality, popularity, achievement, and prosocial behavior. Adolescent friends resemble one another in identity status, educational aspirations, political beliefs, and deviance. But to explore new perspectives, they also befriend agemates with differing attitudes and values.

© MYRLEEN FERGUSON CATE/PHOTOEDIT

- Girls form closer, more exclusive friendships than boys. Very popular and very unpopular early adolescents are more likely to have other-sex friends.
- Gratifying friendships foster self-concept, perspective taking, and identity development; provide a foundation for intimate relationships; offer support in dealing with everyday stresses; and promote good school adjustment. Aggressive friendships seriously undermine development.

Describe categories of peer acceptance, the relationship of social behavior to likability, and ways to help rejected children.

- Self-report measures of **peer acceptance** yield four main categories: **popular children, rejected children, controversial children,** and **neglected children**. Rejected children often experience lasting adjustment problems.
- **Popular-prosocial children** are academically and socially competent; **popular-antisocial children** are aggressive but admired by peers for their sophisticated social skills. **Rejected-aggressive children** display severe conduct problems, in contrast to **rejected-withdrawn children,** who are passive, socially awkward, and at high risk for **peer victimization.** Controversial children blend positive and negative behaviors. Neglected children, though often choosing to play alone, are usually socially competent and well-adjusted.
- Interventions for rejected children include coaching in social skills, intensive academic tutoring, and training in perspective taking and social problem solving. Treatments must also address maladaptive parent–child interaction.

Discuss peer group formation and dating relationships, including their consequences for development.

- By the end of middle childhood, **peer groups** emerge. Within them, children practice cooperation, leadership, followership, and loyalty to collective goals.
- Early-adolescent peer groups are organized into more intimate **cliques**, several of which may form a **crowd** that grants adolescents an identity within the larger social structure of Western schools. Peer group values extend those acquired at home. Mixed-sex cliques provide a supportive context for learning to interact with the other sex.
- Intimacy in dating lags behind that in friendships; early, frequent dating is linked to adjustment problems. Positive relationships with parents and friends contribute to warm romantic ties, which provide practice for more mature bonds.

What factors influence conformity to peer pressure in adolescence?

- Most peer pressure focuses on obvious aspects of peer culture, such as dress and participation in social activities. Resistance to unfavorable peer pressure strengthens with age and is related to adolescent personal characteristics and to authoritative parenting.

Media (p. 629)

Discuss the influence of television on children's development.

- Television is the dominant form of youth media. Boys and low-SES, African-American, and Hispanic children tend to be more frequent viewers. Extensive TV watching is associated with family, peer, and health difficulties.
- Televised violence promotes hostile thoughts and emotions, aggression, and a violent worldview. TV also conveys ethnic and gender stereotypes. Heavy bombardment of children with advertising contributes to many problems, including family stress, overweight and obesity, materialism, and substance use.
- Educational television can promote children's cognitive and academic skills, emotional and social understanding, and prosocial behavior. But heavy viewing of entertainment TV detracts from reading time, school success, and social experiences.

Discuss computer, cell phone, and Internet use by children and adolescents, noting benefits and concerns.

- Computers' educational benefits include word processing for writing and online information-gathering—activities that promote literacy progress and reading achievement. However, girls and low-SES students are disadvantaged in computer opportunities and skills.
- Speed-and-action video games foster selective attention and spatial skills, but violent games promote hostility and aggression. "Passionate" players tend to use games to escape from family and school problems.
- Teenagers' online communication with preexisting friends, through such means as texting and instant messaging, promotes friendship closeness. Using the Internet to interact with strangers can offer vital sources of social support, but teenagers who form online friendships or romances tend to be troubled young people who are at risk for exploitation.

Schooling (p. 637)

How do class and student body size and educational philosophies affect academic and social development?

- Smaller classes in the early elementary grades promote lasting gains in academic achievement. Smaller high schools foster social support and greater school engagement.
- Older students in **traditional classrooms** have a slight edge in academic achievement over those in **constructivist classrooms**, who are advantaged in critical thinking, social and moral maturity, and positive attitudes toward school. But young children in traditional classrooms display poorer study habits and achievement through elementary school.
- Students in **social-constructivist classrooms** benefit both cognitively and socially from collaboration with teachers and peers. In classrooms organized as **communities of learners**, teachers and students draw on one another's expertises to work on complex projects with real-world meaning.

Cite factors that influence adjustment following school transitions in early childhood and in adolescence.

- The capacity to form positive peer and teacher relationships predicts favorable adjustment to kindergarten. Children with weak emotional self-regulation skills and argumentative, aggressive, or peer-avoidant styles tend to establish poor-quality relationships with teachers and peers.
- School transitions in adolescence bring larger, more impersonal school environments, in which both grades and feelings of competence decline. Girls experience more adjustment difficulties after the transition to middle school, which coincides with other life changes (puberty and the beginning of dating). Distressed young people with poor school performance are at risk for continuing academic difficulties and eventual dropout.

Discuss the role of teacher–student interaction and grouping practices in academic achievement.

- Caring, helpful, and stimulating teaching fosters children's motivation and achievement. **Educational self-fulfilling prophecies** are particularly strong in classrooms emphasizing competition and public evaluation, and they have a greater impact on low achievers.
- Homogeneous grouping in elementary school is linked to poorer-quality instruction and declines in self-esteem and achievement for children in low-ability groups. Multigrade classrooms promote favorable school attitudes, achievement, and self-esteem.
- By high school, some homogeneous grouping is educationally necessary, but in the United States, high school tracking extends earlier educational inequalities. Low-SES students are at risk for unfair placement in non-college tracks.

Under what conditions is placement of students with special needs in regular classrooms successful, and how can schools increase parent involvement in education?

- Effective placement of students with mild mental retardation and **learning disabilities** in **inclusive classrooms** depends on learning experiences tailored to children's academic needs and promotion of positive peer relations.

© ELLEN B. SENISI PHOTOGRAPHY

- Schools can increase parent involvement by fostering parent–teacher relationships, building bridges between minority home cultures and the school culture, and involving parents in school governance.

How well are American young people achieving compared with their counterparts in other industrialized nations, and what problems do non-college-bound youths face in preparing for a vocation?

- In international studies, U.S. students typically display average or below-average performance. Compared with education in top-achieving countries, U.S. instruction is less focused on high-level reasoning and critical thinking. Whereas high-achieving nations emphasize equal opportunity for all, U.S. low-income and ethnic minority students typically attend inferior-quality schools.
- Unlike some European nations, the United States has no widespread vocational training system to help non-college-bound adolescents prepare for skilled business and industrial occupations and manual trades.

rejected-aggressive children (p. 619)
rejected-withdrawn children (p. 620)
rough-and-tumble play (p. 610)
social-constructivist classroom (p. 640)
traditional classroom (p. 638)

Glossary

A

accommodation In Piaget's theory, that part of adaptation in which new schemes are created or old ones adjusted to produce a better fit with the environment. Distinguished from *assimilation.* (p. 227)

acculturative stress Psychological distress resulting from conflict between an individual's minority culture and the host culture. (p. 475)

achievement motivation The tendency to persist at challenging tasks. (p. 465)

achievement test A test that assesses actual knowledge and skill attainment. Distinguished from *aptitude test.* (p. 328)

adaptation In Piaget's theory, the process of building schemes through direct interaction with the environment. Consists of two complementary activities: *assimilation* and *accommodation.* (p. 227)

affordances The action possibilities that a situation offers an organism with certain motor capabilities. Discovery of affordances plays a vital role in perceptual differentiation. (p. 168)

age of viability The age at which a fetus born early first has a chance of survival, occurring sometime between 22 and 26 weeks. (p. 92)

alcohol-related neurodevelopmental disorder (ARND) The least severe form of fetal alcohol spectrum disorder, involving brain injury but with typical physical growth and absence of facial abnormalities. Distinguished from *fetal alcohol syndrome (FAS)* and *partial fetal alcohol syndrome (p-FAS).* (p. 99)

allele Each of two or more forms of a gene located at the same place on the chromosomes. (p. 77)

amnion The inner membrane that encloses the prenatal organism in amniotic fluid, which helps keep temperature constant and provides a cushion against jolts caused by the mother's movement. (p. 89)

amodal sensory properties Information that is not specific to a single modality but that overlaps two or more sensory systems, such as rate, rhythm, duration, intensity, temporal synchrony (for vision and hearing), and texture and shape (for vision and touch). (p. 166)

amygdala An inner-brain structure that plays a central role in processing emotional information. (p. 190)

analogical problem solving Applying a solution strategy from one problem to other relevant problems. (p. 235)

androgens Hormones released chiefly by boys' testes, and in smaller amounts by the adrenal glands, that influence the pubertal growth spurt and stimulate muscle growth, body and facial hair, and male sex characteristics. (p. 183)

androgyny The gender identity held by individuals who score high on both traditionally masculine and traditionally feminine personality characteristics. (p. 547)

anorexia nervosa An eating disorder in which young people, mainly females, starve themselves because of a compulsive fear of getting fat and an extremely distorted body image. (p. 210)

A-not-B search error The error made by 8- to 12-month-olds who, after an object is moved from one hiding place (A) to another hiding place (B), search for it incorrectly in the first hiding place (A). (p. 229)

Apgar Scale A rating system used to assess a newborn baby's physical condition immediately after birth on the basis of five characteristics: heart rate, respiratory effort, reflex irritability, muscle tone, and color. (p. 109)

aptitude test A test that assesses an individual's potential to learn a specialized activity. Distinguished from *achievement test.* (p. 328)

assimilation In Piaget's theory, that part of adaptation in which the external world is interpreted in terms of current schemes. Distinguished from *accommodation.* (p. 227)

associative play A form of social interaction in which children engage in separate activities but interact by exchanging toys and commenting on one another's behavior. Distinguished from *nonsocial activity, parallel play,* and *cooperative play.* (p. 608)

attachment The strong, affectionate tie that humans have with special people in their lives, which leads them to feel pleasure when interacting with those people and to be comforted by their nearness in times of stress. (p. 428)

Attachment Q-Sort A method for assessing the quality of attachment between ages 1 and 4 years through home observations of a variety of attachment-related behaviors. (p. 431)

attention-deficit hyperactivity disorder (ADHD) A childhood disorder involving inattention, impulsivity, and excessive motor activity, often leading to academic and social problems. (p. 290)

attribution retraining An intervention that uses adult feedback to encourage learned-helpless children to believe that they can overcome failure through effort. (p. 467)

attributions Common, everyday explanations for the causes of behavior. (p. 464)

authoritarian child-rearing style A child-rearing style that is low in acceptance and involvement, high in coercive behavioral control, and low in autonomy granting. Distinguished from *authoritative, permissive,* and *uninvolved child-rearing styles.* (p. 574)

authoritative child-rearing style A child-rearing style that is high in acceptance and involvement, emphasizes adaptive control techniques, and includes gradual, appropriate autonomy granting. Distinguished from *authoritarian, permissive,* and *uninvolved child-rearing styles.* (p. 573)

autobiographical memory Representations of one-time events that are long-lasting because they are imbued with personal meaning. (p. 298)

automatic processes In information processing, processes that are so well-learned that they require no space in working memory and, therefore, permit the individual to focus on other information while simultaneously performing them. (p. 280)

autonomy In adolescence, a sense of oneself as a separate, self-governing individual. Involves relying more on oneself and less on parents for support and guidance and engaging in careful, well-reasoned decision making. (p. 577)

autosomes The 22 matching chromosome pairs in each human cell. (p. 76)

avoidant attachment The attachment pattern characterizing infants who seem unresponsive to the parent when she is present, are usually not distressed when she leaves, and avoid the parent when she returns. Distinguished from *secure, resistant,* and *disorganized/disoriented attachment.* (p. 430)

B

babbling Babies' repetition of consonant–vowel combinations, often in long strings, beginning around 6 months of age. (p. 370)

basic emotions Emotions such as happiness, interest, surprise, fear, anger, sadness, and disgust that are universal in humans and other primates and have a long evolutionary history of promoting survival. (p. 406)

behavioral genetics A field devoted to uncovering the contributions of nature and nurture to the diversity of human traits and abilities. (p. 119)

behaviorism An approach that regards directly observable events—stimuli and responses—as the appropriate focus of study and that views the development of behavior as taking place through classical and operant conditioning. (p. 17)

behavior modification Procedures that combine conditioning and modeling to eliminate undesirable behaviors and increase desirable responses. (p. 18)

belief–desire theory of mind The more sophisticated theory of mind that emerges around age 4, in which children understand that both beliefs and desires determine behavior. (p. 452)

biased sampling Failure to select participants who are representative of the population of interest in a study. (p. 61)

bicultural identity The identity constructed by individuals who explore and adopt values from both their family's subculture and the dominant culture. (p. 475)

blended, or **reconstituted, family** A family structure formed through cohabitation or remarriage that includes parent, child, and steprelatives. (p. 594)

body image Conception of and attitude toward one's physical appearance. (p. 209)

brain plasticity The capacity of various parts of the cerebral cortex to take over functions of damaged regions. Declines as hemispheres of the cerebral cortex lateralize. (p. 187)

breech position A position of the baby in the uterus that would cause the buttocks or feet to be delivered first. (p. 113)

Broca's area A structure located in the left frontal lobe of the cerebral cortex that supports grammatical processing and language production. (p. 363)

bulimia nervosa An eating disorder in which individuals, mainly girls but also including some gay and bisexual boys, engage in strict dieting and excessive exercise accompanied by binge eating, often followed by deliberate vomiting and purging with laxatives. (p. 211)

C

canalization The tendency of heredity to restrict the development of some characteristics to just one or a few outcomes. (p. 122)

cardinality The mathematical principle stating that the last word in a counting sequence indicates the quantity of items in the set. (p. 311)

carrier A heterozygous individual who can pass a recessive trait to his or her offspring. (p. 77)

categorical self Classification of the self on the basis of perceptually distinct attributes and behaviors, such as age, sex, physical characteristics, and goodness and badness. Develops between 18 and 30 months. Distinguished from *remembered self, enduring self,* and *inner self.* (p. 450)

categorical speech perception The tendency to perceive as identical a range of sounds that belong to the same phonemic class. (p. 368)

central conceptual structures In Case's neo-Piagetian theory, networks of concepts and relations that permit children to think about a wide range of situations in more advanced ways. Generated once the schemes of a Piagetian stage become sufficiently automatic and brain development further increments processing speed, freeing enough space in working memory to consolidate schemes into an improved representational form. (p. 283)

central executive In information processing, the conscious, reflective part of the mental system, which directs the flow of information by deciding what to attend to; coordinating incoming information with information already in the system; and selecting, applying, and monitoring strategies that facilitate memory storage, comprehension, reasoning, and problem solving. (p. 279)

centration In Piaget's theory, the tendency to focus on one aspect of a situation, neglecting other important features. (p. 245)

cephalocaudal trend An organized pattern of physical growth and motor control in which the head develops ahead of the lower part of the body ("head to tail"). Distinguished from *proximodistal trend.* (p. 176)

cerebellum A structure at the rear and base of the brain that aids in balance and control of body movement. (p. 189)

cerebral cortex The largest, most complex structure of the human brain, containing the greatest number of neurons and synapses, which accounts for the highly developed intelligence of the human species. (p. 186)

child development An area of study devoted to understanding constancy and change from conception through adolescence. (p. 4)

child-rearing styles Combinations of parenting behaviors that occur over a wide range of situations, creating an enduring child-rearing climate. (p. 573)

chorion The outer membrane that forms a protective covering around the prenatal organism. It sends out tiny hairlike villi, from which the placenta begins to develop. (p. 89)

chromosomes Rodlike structures in the cell nucleus that store and transmit genetic information. (p. 73)

chronosystem In ecological systems theory, temporal changes in children's environments, either externally imposed or arising from within the child, that produce new conditions affecting development. Distinguished from *microsystem, mesosystem, exosystem,* and *macrosystem.* (p. 28)

circular reaction In Piaget's theory, a means of adapting schemes in which babies try to repeat a chance event originally caused by their own motor activity. (p. 228)

classical conditioning A form of learning that involves associating a neutral stimulus with a stimulus that leads to a reflexive response. Once the nervous system makes the connection between the two stimuli, the new stimulus will produce the behavior by itself. (p. 140)

clinical interview An interview method in which the researcher uses a flexible, conversational style to probe for the participant's point of view. (p. 46)

clinical, or **case study, method** A research method in which the aim is to obtain as complete a picture as possible of one child's psychological functioning by bringing together a wide range of information, including interviews, observations, test scores, and sometimes neurobiological measures. (p. 50)

clique A group of about five to eight members who are friends and, therefore, tend to resemble one another in family background, attitudes, values, and interests. (p. 623)

code switching A strategy in which bilingual individuals produce an utterance in one language that contains one or more "guest" words from the other, without violating the grammar of either language. (p. 396)

cognition The inner processes and products of the mind that lead to "knowing," including all mental activity—attending, remembering, symbolizing, categorizing, planning, reasoning, problem solving, creating, and fantasizing. (p. 225)

cognitive-developmental theory Piaget's theory of development, which views children as actively constructing knowledge as they manipulate and explore their world and regards cognitive development as taking place in stages. (p. 19)

cognitive maps Mental representations of familiar large-scale spaces, such as school or neighborhood. (p. 250)

cognitive self-regulation The process of continuously monitoring and controlling progress toward a goal—planning, checking outcomes, and redirecting unsuccessful efforts. (p. 304)

cohort effects The effects of cultural–historical change on the accuracy of longitudinal and cross-sectional research findings. Results based on one cohort—children developing in the same time period who are influenced by particular cultural and historical conditions—may not apply to other cohorts. (p. 62)

collectivist societies Societies in which people define themselves as part of a group and stress group goals over individual goals. Distinguished from *individualistic societies.* (p. 35)

community of learners A classroom in which both teachers and students have the authority to define and resolve problems, drawing on one another's expertise and that of others as they work toward project goals, which often address complex real-world issues. (p. 640)

compliance Voluntary obedience to requests and commands. (p. 514)

componential analysis Research that combines the psychometric and information-processing approaches in an effort to identify relationships between aspects (or components) of information processing and children's intelligence test performance. (p. 323)

comprehension In language development, the words children understand. Distinguished from *production.* (p. 376)

concrete operational stage Piaget's third stage, extending from about 7 to 11 years, during which thought becomes logical, flexible, and organized in its application to concrete information. (p. 249)

conditioned response (CR) In classical conditioning, a new response produced by a conditioned stimulus (CS) that is similar to the unconditioned, or reflexive, response (UCR). (p. 140)

conditioned stimulus (CS) In classical conditioning, a neutral stimulus that, through pairing with an unconditioned stimulus (UCS), leads to a new, conditioned response (CR). (p. 140)

confounding variables Variables so closely associated that their effects on an outcome cannot be distinguished. (p. 57)

conservation The understanding that certain physical characteristics of objects remain the same, even when their outward appearance changes. (p. 244)

construction In moral development, the process of actively attending to and interrelating multiple perspectives on situations in which social conflicts arise and thereby attaining new moral understandings. (p. 495)

constructivist approach Piaget's view of cognitive development, in which children discover, or construct, virtually all knowledge about their world through their own activity. (p. 226)

constructivist classroom A classroom grounded in Piaget's view of children as active learners who construct their own knowledge. Characterized by richly equipped learning centers, small groups and individuals solving self-chosen problems, a teacher who guides and supports in response to children's needs, and evaluation that considers students' progress in relation to their own prior development. Distinguished from *traditional classroom* and *social constructivist classroom.* (p. 638)

contexts Unique combinations of personal and environmental circumstances that can result in different paths of development. (p. 8)

continuous development The view that development is a process of gradually adding more of the same types of skills that were there to begin with. Distinguished from *discontinuous development.* (p. 7)

contrast sensitivity A general principle accounting for early pattern preferences, which states that if babies can detect a difference in contrast between two or more patterns, they will prefer the one with more contrast. (p. 161)

control deficiency Inability to control, or execute, a mental strategy effectively. Distinguished from *production deficiency, utilization deficiency,* and *effective strategy use.* (p. 288)

controversial children Children who get many votes, both positive and negative, on self-report measures of peer acceptance, indicating that they are both liked and disliked. Distinguished from *popular, rejected,* and *neglected children.* (p. 618)

conventional level Kohlberg's second level of moral development, in which moral understanding is based on conforming to social rules to ensure positive human relationships and maintain societal order. (p. 501)

convergent thinking Thinking that involves arriving at a single correct answer to a problem; the type of thinking emphasized on intelligence tests. Distinguished from *divergent thinking.* (p. 350)

cooing Pleasant vowel-like noises made by infants, beginning around 2 months of age. (p. 370)

cooperative learning Collaboration on a task by a small group of peers who work toward common goals by resolving differences of opinion, sharing responsibilities, and providing one another with sufficient explanations to correct misunderstandings. (p. 271)

cooperative play A form of social interaction in which children orient toward a common goal, such as acting out a make-believe theme. Distinguished from *nonsocial activity, parallel play,* and *associative play.* (p. 608)

coparenting Parents' mutual support of each other's parenting behaviors. (p. 569)

core knowledge perspective A perspective that states that infants begin life with innate, special-purpose knowledge systems, or core domains of thought, each of which permits a ready grasp of new, related information and therefore supports early, rapid development of certain aspects of cognition. (p. 261)

coregulation A form of supervision in which parents exercise general oversight while permitting children to take charge of moment-by-moment decision making. (p. 577)

corpus callosum The large bundle of fibers connecting the two cerebral hemispheres. (p. 190)

correlation coefficient A number, ranging from +1.00 to –1.00, that describes the strength and direction of the relationship between two variables. (p. 56)

correlational design A research design in which the investigator gathers information on individuals without altering their experiences and then examines relationships between participants' characteristics and their behavior or development. Does not permit inferences about cause and effect. (p. 55)

creativity The ability to produce work that is original yet appropriate—something that others have not thought of but that is useful in some way. (p. 350)

crossing over During meiosis, the exchange of genes between chromosomes next to each other. (p. 75)

cross-sectional design A research design in which groups of participants differing in age are studied at the same point in time. Distinguished from *longitudinal design.* (p. 62)

crowd A large, loosely organized social group consisting of several cliques, with membership based on reputation and stereotype. (p. 623)

crystallized intelligence In Cattell's theory, a form of intelligence involving skills that depend on accumulated knowledge and experience, good judgment, and mastery of social customs. Distinguished from *fluid intelligence.* (p. 321)

D

debriefing Providing a full account and justification of research activities to participants after the conclusion of a study in which deception was used. (p. 69)

deferred imitation The ability to remember and copy the behavior of models who are not present. (p. 230)

delay of gratification Ability to wait for an appropriate time and place to engage in a tempting act. (p. 514)

deoxyribonucleic acid (DNA) Long, double-stranded molecules that make up chromosomes. (p. 74)

dependent variable The variable the researcher expects to be influenced by the independent variable in an experiment. (p. 56)

desire theory of mind The theory of mind of 2- to 3-year-olds, who assume that people always act in ways consistent with their desires but who do not understand the influence on behavior of interpretive mental states, such as beliefs. (p. 452)

developmental cognitive neuroscience An area of investigation that brings together researchers from psychology, biology, neuroscience, and medicine to study the relationship between changes in the brain and the developing child's cognitive processing and behavior patterns. (p. 23)

developmental quotient (DQ) A score on an infant intelligence test, computed in the same manner as an IQ but labeled more conservatively because it does not tap the same dimensions of intelligence measured in older children. (p. 329)

developmental science An interdisciplinary field devoted to the study of all changes humans experience throughout the lifespan. (p. 4)

developmentally appropriate practice Research-based standards devised by the National Association for the Education of Young Children that specify program characteristics that meet the developmental and individual needs of young children of varying ages. (p. 443)

differentiation theory The view that perceptual development involves the detection of increasingly fine-grained, invariant features of the environment. (p. 168)

difficult child A child whose temperament is characterized by irregular daily routines, slow acceptance of new experiences, and a tendency to react negatively and intensely. Distinguished from *easy child* and *slow-to-warm-up child.* (p. 420)

discontinuous development The view that development is a process in which new ways of understanding and responding to the world emerge at specific times. Distinguished from *continuous development.* (p. 7)

disorganized/disoriented attachment The attachment pattern reflecting the greatest insecurity, characterizing infants who show confused, contradictory behaviors when reunited with the parent after a separation. Distinguished from *secure, avoidant,* and *resistant attachment.* (p. 431)

displaced reference The realization that words can be used to cue mental images of things that are not physically present. (p. 235)

distance curve A growth curve that plots the average size of a sample of children at each age, indicating typical yearly progress toward maturity. Distinguished from *velocity curve.* (p. 176)

divergent thinking Thinking that involves generating multiple and unusual possibilities when faced with a task or problem; associated with creativity. Distinguished from *convergent thinking.* (p. 350)

dominance hierarchy A stable ordering of group members that predicts who will win when conflict arises. (p. 610)

dominant cerebral hemisphere The hemisphere of the cerebral cortex with greater capacity to carry out skilled motor action and where other important abilities (language) generally are located. In right-handed individuals, the left hemisphere is dominant; in left-handed individuals, language is often shared between the hemispheres. (p. 189)

dominant–recessive inheritance A pattern of inheritance in which, under heterozygous conditions, the influence of only one allele is apparent. (p. 77)

dual representation The ability to view a symbolic object as both an object in its own right and a symbol. (p. 243)

dynamic assessment An approach to testing consistent with Vygotsky's zone of proximal development in which an adult introduces purposeful teaching into the testing situation to find out what the child can attain with social support. (p. 342)

dynamic systems perspective A view that regards the child's mind, body, and physical and social worlds as an integrated system that guides mastery of new skills. A change in any part of the system disrupts the current organism–environment relationship, leading the child to reorganize his or her behavior so the components of the system work together again but in a more complex, effective way. (p. 30)

dynamic systems theory of motor development A theory that views new motor skills as reorganizations of previously mastered skills, which lead to more effective ways of exploring and controlling the environment. Each new skill is a joint product of central nervous system development, the body's movement possibilities, the child's goals, and environmental supports for the skill. (p. 148)

E

Early Head Start A U.S. federal program that provides infants and toddlers who have serious developmental problems or are at risk for problems because of poverty with coordinated early intervention services, including child care, educational experiences, parenting education, family social support, and health care. (p. 349)

easy child A child whose temperament is characterized by establishment of regular routines in infancy, general cheerfulness, and easy adaptation to new experiences. Distinguished from *difficult child* and *slow-to-warm-up child.* (p. 420)

ecological systems theory Bronfenbrenner's theory, which views the child as developing within a complex system of relationships affected by multiple levels of the surrounding environment, from immediate settings of family and school to broad cultural values, laws, customs, and resources. (p. 26)

educational self-fulfilling prophecies Teachers' positive or negative views of individual children, who tend to adopt and start to live up to those views. (p. 643)

effective strategy use Consistent use of a mental strategy, with corresponding improvement in performance. Distinguished from *production deficiency, control deficiency,* and *utilization deficiency.* (p. 289)

effortful control The self-regulatory dimension of temperament, involving voluntary suppression of a dominant response in order to plan and execute a more adaptive response. (p. 421)

egocentrism Failure to distinguish others' symbolic viewpoints from one's own. (p. 244)

elaboration A memory strategy that involves creating a relationship, or shared meaning, between two or more pieces of information that do not belong to the same category. (p. 293)

embryo The prenatal organism from 2 to 8 weeks after conception—the period when the groundwork is laid for all body structures and internal organs. (p. 91)

emergent literacy Children's active efforts to construct literacy knowledge through informal experiences. (p. 307)

emergentist coalition model The view that word-learning strategies emerge out of children's efforts to decipher language, during which they draw on a coalition of perceptual, social, and linguistic cues that shift in importance with age. (p. 383)

emotion A rapid appraisal of the personal significance of a situation, which prepares the individual for action. (p. 401)

emotional display rules A society's rules specifying when, where, and how it is appropriate to express emotions. (p. 412)

emotional intelligence A set of emotional abilities that enable individuals to process and adapt to emotional information, measured by tapping emotional skills that enable people to manage their own emotions and interact competently with others. (p. 327)

emotional self-regulation Strategies for adjusting our emotional state to a comfortable level of intensity so we can accomplish our goals. (p. 409)

emotion-centered coping A general strategy for managing emotion that is internal, private, and aimed at controlling distress when little can be done to change an outcome. Distinguished from *problem-centered coping.* (p. 412)

empathy The ability to take another individual's emotional perspective and to feel with that person, or respond emotionally in a similar way. (p. 416)

enduring self A view of the self as persisting over time. Distinguished from *categorical self, remembered self,* and *inner self.* (p. 451)

entity view of ability The view that ability is a fixed characteristic that cannot be improved through effort; associated with learned helplessness. Distinguished from *incremental view of ability.* (p. 465)

environmental cumulative deficit hypothesis The view that the negative effects of underprivileged rearing conditions increase the longer children remain in those conditions, making early cognitive deficits harder to overcome. (p. 331)

epigenesis Development resulting from ongoing, bidirectional exchanges between heredity and all levels of the environment. (p. 124)

epiphyses Growth centers at the ends of each of the long bones of the body, where new cartilage cells are produced and gradually harden. (p. 178)

episodic memory Recollections of specific personally experienced events. (p. 297)

equilibration In Piaget's theory, the back-and-forth movement between equilibrium and disequilibrium that produces more effective schemes. (p. 227)

estrogens Hormones released by girls' ovaries that cause the breasts, uterus, and vagina to mature, the body to take on feminine proportions, and fat to accumulate. Estrogens also contribute to regulation of the menstrual cycle. (p. 183)

ethnic identity A sense of ethnic group membership, and attitudes and feelings associated with that membership, as an enduring aspect of the self. (p. 475)

ethnography A descriptive, qualitative research method directed at understanding a culture or a distinct social group through participant observation—living with group members and taking field notes for an extended period. (p. 52)

ethological theory of attachment A theory formulated by Bowlby that recognizes the infant's emotional tie to the caregiver as an evolved response that promotes survival. (p. 428)

ethology An approach concerned with the adaptive, or survival, value of behavior and its evolutionary history. (p. 23)

event sampling A form of systematic observation in which the researcher records all instances of a particular behavior during a specified time period. (p. 44)

evolutionary developmental psychology An approach that seeks to understand the adaptive value of species-wide cognitive, emotional, and social competencies as those competencies change with age. (p. 24)

executive function In information processing, the set of cognitive operations and strategies necessary for self-initiated, purposeful behavior in relatively novel, challenging situations. (p. 281)

exosystem In ecological systems theory, social settings that do not contain children but that affect children's experiences in immediate settings—for example, parents' workplace, health and welfare services in the community, and parents' social networks. Distinguished from *microsystem, mesosystem, macrosystem,* and *chronosystem.* (p. 28)

expansions Adult responses that elaborate on children's speech, increasing its complexity. (p. 389)

experience-dependent brain growth Growth and refinement of established brain structures as a result of specific learning experiences that vary widely across individuals and cultures. Distinguished from *experience-expectant brain growth.* (p. 191)

experience-expectant brain growth The young brain's rapidly developing organization, which depends on ordinary experiences—opportunities to interact with people, hear language and other sounds, see and touch objects, and move about and explore the environment. Distinguished from *experience-dependent brain growth.* (p. 191)

experimental design A research design in which the investigator randomly assigns participants to two or more treatment conditions and studies the effect that manipulating an independent variable has on a dependent variable. Permits inferences about cause and effect. (p. 56)

expressive style A style of early language learning in which toddlers use language mainly to talk about their own and others' feelings and needs, with an initial vocabulary emphasizing social formulas and pronouns. Distinguished from *referential style.* (p. 378)

expressive traits Personality traits emphasizing warmth, caring, and sensitivity, that are widely regarded as feminine. Distinguished from *instrumental traits.* (p. 530)

extended-family household A household in which one or more adult relatives live with the parent–child nuclear family unit. (p. 583)

external validity The degree to which research findings generalize to settings and participants outside the original study. Distinguished from *internal validity.* (p. 55)

extinction In classical conditioning, decline of the conditioned response (CR) as a result of presenting the conditioned stimulus (CS) enough times, without being paired with the unconditioned stimulus (UCS). (p. 140)

F

factor analysis A complicated correlational procedure that identifies sets of test items that cluster together, called factors. Used to investigate whether intelligence is one trait or an assortment of abilities. (p. 321)

fast-mapping Children's ability to connect a new word with an underlying concept after only a brief encounter. (p. 377)

fetal alcohol spectrum disorder (FASD) A range of physical, mental, and behavioral outcomes caused by prenatal alcohol exposure. (p. 98)

fetal alcohol syndrome (FAS) The most severe form of fetal alcohol spectrum disorder, distinguished by slow physical growth, facial abnormalities, and brain injury; usually affects children whose mothers drank heavily throughout pregnancy. Distinguished from *partial fetal alcohol syndrome (p-FAS)* and *alcohol-related neurodevelopmental disorder (ARND).* (p. 98)

fetus The prenatal organism from the ninth week to the end of pregnancy—the period in which body structures are completed and dramatic growth in size occurs. (p. 92)

field experiment A research design in which participants are randomly assigned to treatment conditions in natural settings. (p. 58)

fluid intelligence In Cattell's theory, a form of intelligence that depends primarily on basic information-processing skills—ability to detect relationships among stimuli, speed of analyzing information, and capacity of working memory. Distinguished from *crystallized intelligence.* (p. 321)

Flynn effect An increase in IQ from one generation to the next. (p. 338)

formal operational stage Piaget's highest stage, beginning around age 11, in which adolescents develop the capacity for abstract, systematic, scientific thinking. (p. 253)

fraternal, or **dizygotic, twins** Twins resulting from the release and fertilization of two ova. Genetically, they are no more alike than ordinary siblings. Distinguished from *identical,* or *monozygotic, twins.* (p. 76)

friendship A close relationship involving companionship in which each partner wants to be with the other. (p. 613)

functionalist approach to emotion A perspective emphasizing that the broad function of emotions is to energize behavior aimed at attaining personal goals. (p. 401)

fuzzy-trace theory A theory proposing that when we first encode information, we automatically reconstruct it into a vague, fuzzy version, or gist, which preserves essential meaning without details and is especially useful for reasoning. (p. 296)

G

gametes Sex cells, or sperm and ova, which contain half as many chromosomes as regular body cells. (p. 75)

gender consistency Kohlberg's final stage of gender understanding, in which children in the late preschool and early school years understand that sex is biologically based and remains the same even if a person dresses in "cross-gender" clothes or engages in nontraditional activities. (p. 548)

gender constancy A full understanding of the biologically based permanence of gender, which combines three understandings: *gender labeling*, *gender stability*, and *gender consistency*. (p. 548)

gender identity An image of oneself as relatively masculine or feminine in characteristics. (p. 530)

gender intensification The increased gender stereotyping of attitudes and behavior and movement toward a more traditional gender identity that sometimes occurs with the arrival of adolescence. (p. 550)

gender labeling Kohlberg's first stage of gender understanding, in which children in the early preschool years can correctly label their own sex and that of others but do not understand that sex is biologically based and permanent. (p. 548)

gender roles The reflection of gender stereotypes in everyday behavior. (p. 530)

gender schema theory An information-processing approach to gender typing that explains how environmental pressures and children's cognitions work together to shape gender-typing. (p. 551)

gender stability Kohlberg's second stage of gender understanding, in which preschoolers grasp the stability of sex over time. (p. 548)

gender-stereotype flexibility The belief that both males and females can display a gender-stereotyped personality trait or activity. (p. 533)

gender stereotypes Widely held beliefs about characteristics deemed appropriate for males and females. (p. 530)

gender typing Any association of objects, activities, roles, or traits with biological sex in ways that conform to cultural stereotypes of gender. (p. 530)

gene A segment of a DNA molecule that contains instructions for production of various proteins that contribute to body growth and functioning. (p. 74)

gene–environment correlation The idea that heredity influences the environments to which individuals are exposed. (p. 122)

gene–environment interaction The idea that individuals' genetic makeup influences their responsiveness to qualities of the environment (p. 121)

general intelligence In Spearman's theory, a common underlying factor, called *g,* believed to influence all aspects of intelligence. Distinguished from *specific intelligence.* (p. 321)

generalized other A blend of what we imagine important people in our lives think of us, crucial to developing a self-concept based on personality traits. (p. 459)

genetic counseling A communication process designed to help couples assess their chances of giving birth to a baby with a hereditary disorder and choose the best course of action in view of risks and family goals. (p. 84)

genomic imprinting A pattern of inheritance in which alleles are imprinted, or chemically marked, in such a way that one pair member is activated, regardless of its makeup. (p. 80)

genotype An individual's genetic makeup. Distinguished from *phenotype.* (p. 73)

gifted Displaying exceptional intellectual strengths, including high IQ, creativity, and talent. (p. 350)

gist In fuzzy-trace theory, a vague, fuzzy representation of information that preserves essential meaning without details and is especially useful for reasoning. (p. 296)

glial cells Cells responsible for myelination of neural fibers, which improves the efficiency of message transfer. (p. 186)

goodness-of-fit model Thomas and Chess's model, which states that an effective match, or "good fit," between a child's temperament and the child-rearing environment promotes more adaptive functioning, whereas a "poor fit" results in adjustment problems. (p. 426)

grammar The component of language concerned with *syntax,* the rules by which words are arranged into sentences, and *morphology,* the use of grammatical markers indicating number, tense, case, person, gender, active or passive voice, and other meanings. (p. 360)

grammatical morphemes In language development, small markers that change the meaning of sentences, as in "John*'s* dog" and "he *is* eating." (p. 386)

growth faltering Failure of an infant to grow normally, characterized by weight, height, and head circumference substantially below age-related growth norms and by withdrawn, apathetic behavior. A disturbed parent–infant relationship is often a contributing factor. (p. 202)

growth hormone (GH) A pituitary hormone that affects the development of all body tissues except the central nervous system and the genitals. (p. 182)

guided participation Shared endeavors between more expert and less expert participants, regardless of the precise features of communication. A broader concept than *scaffolding.* (p. 268)

H

habituation A gradual reduction in the strength of a response due to repetitive stimulation. (p. 142)

heritability estimate A measure of the extent to which individual differences in complex traits, such as intelligence or personality in a specific population, are due to genetic factors. (p. 120)

heteronomous morality Piaget's first stage of moral development, in which children view rules as handed down by authorities, as having a permanent existence, as unchangeable, and as requiring strict obedience. (p. 496)

heterozygous Having two different alleles at the same place on a pair of chromosomes. Distinguished from *homozygous.* (p. 77)

hierarchical classification The organization of objects into classes and subclasses on the basis of similarities and differences. (p. 245)

hippocampus An inner-brain structure that plays a vital role in memory and in images of space that help us find our way. (p. 190)

Home Observation for Measurement of the Environment (HOME) A checklist for gathering information about the quality of children's home lives through observation and parental interview. (p. 344)

homozygous Having two identical alleles at the same place on a pair of chromosomes. Distinguished from *heterozygous.* (p. 77)

hypothalamus A structure located at the base of the brain that initiates and regulates pituitary secretions. (p. 181)

hypothesis A prediction drawn from a theory. (p. 41)

hypothetico-deductive reasoning A formal operational problem-solving strategy in which adolescents begin with a hypothesis, or prediction, about variables that might affect an outcome. From the hypothesis, they *deduce* logical, testable inferences. Then they systematically isolate and combine variables to see which of those inferences are confirmed in the real world. (p. 253)

I

ideal reciprocity A standard of fairness based on mutuality of expectations, as expressed in the Golden Rule: "Do unto others as you would have them do unto you." (p. 497)

identical, or **monozygotic, twins** Twins that result when a zygote, during early cell duplication, separates into two clusters of cells with the same genetic makeup. Distinguished from *fraternal,* or *dizygotic, twins.* (p. 76)

identity A well-organized conception of the self that defines who one is, what one values, and the directions one wants to pursue in life. (p. 468)

identity achievement The identity status of individuals who, after a period of exploration, have committed themselves to self-chosen values and goals. Distinguished from *identity moratorium, identity foreclosure,* and *identity diffusion.* (p. 470)

identity diffusion The identity status of individuals who do not engage in exploration and are not committed to values and goals. Distinguished from *identity achievement, identity moratorium,* and *identity foreclosure.* (p. 470)

identity foreclosure The identity status of individuals who, without engaging in exploration, commit themselves to ready-made values and goals chosen for them by authority figures. Distinguished from *identity achievement, identity moratorium,* and *identity diffusion.* (p. 470)

identity moratorium The identity status of individuals who are exploring, but not yet committed to, self-chosen values and goals. Distinguished from *identity achievement, identity foreclosure,* and *identity diffusion.* (p. 470)

illocutionary intent In conversation, what a speaker means to say, even if the form of the utterance is not perfectly consistent with it. (p. 390)

imaginary audience Adolescents' belief that they are the focus of everyone else's attention and concern. (p. 255)

imitation Learning by copying the behavior of another person. Also known as modeling or observational learning. (p. 145)

inclusive classroom A classroom in which students with learning difficulties learn alongside typical students in a regular educational setting for part or all of the school day. (p. 646)

incomplete dominance A pattern of inheritance in which both alleles are expressed in the phenotype, resulting in a combined trait, or one that is intermediate between the two. (p. 79)

incremental view of ability The view that ability can increase through effort; associated with mastery-oriented attributions. Distinguished from *entity view of ability.* (p. 465)

independent variable The variable that the researcher expects to cause changes in another variable in an experiment. Distinguished from *dependent variable.* (p. 56)

individualistic societies Societies in which people think of themselves as separate entities and are largely concerned with their own personal needs. Distinguished from *collectivist societies.* (p. 35)

induction A type of discipline in which the adult helps the child notice others' feelings by pointing out the effects of the child's misbehavior on others, especially noting their distress and making clear that the child caused it. (p. 489)

infant-directed speech (IDS) A form of communication used by adults in many countries when speaking to babies, consisting of short sentences with high-pitched, exaggerated expression, clear pronunciation, distinct pauses between speech segments, clear gestures to support verbal meaning, and repetition of new words in a variety of contexts. (p. 369)

infant mortality The number of deaths in the first year of life per 1,000 live births. (p. 118)

infantile amnesia The inability of most people to retrieve events that happened to them before age 3. (p. 301)

information processing An approach that views the human mind as a symbol-manipulating system through which information flows and that regards cognitive development as a continuous process. (p. 21)

informed consent The right of research participants, including children, to have explained to them, in language they can understand, all aspects of a study that might affect their willingness to participate. (p. 67)

inhibited, or **shy, child** A child who tends to react negatively to and withdraw from novel stimuli. Distinguished from *uninhibited,* or *sociable, child.* (p. 421)

inhibition The ability to control internal and external distracting stimuli, which helps children remember, reason, solve problems, and manage their behavior in social situations. (p. 287)

inner self Awareness of the self's private thoughts and imaginings. Distinguished from *categorical self, remembered self,* and *enduring self.* (p. 452)

instrumental traits Personality traits reflecting competence, rationality, and assertiveness, widely regarded as masculine. Distinguished from *expressive traits.* (p. 530)

intelligence quotient (IQ) A score that indicates the extent to which an individual's raw score (number of items passed) on an intelligence test deviates from the typical performance of same-age individuals. (p. 330)

intentional, or **goal-directed, behavior** A sequence of actions in which schemes are deliberately coordinated to solve a problem. (p. 229)

interactional synchrony A form of communication in which the caregiver responds to infant signals in a well-timed, rhythmic, appropriate fashion, and both partners match emotional states, especially positive ones. (p. 434)

intermodal perception Perception that combines simultaneous input from more than one modality, or sensory system, resulting in an integrated whole. (p. 166)

internal validity The degree to which conditions internal to the design of a research study permit an accurate test of the researcher's hypothesis or question. Distinguished from *external validity.* (p. 55)

internal working model A set of expectations about the availability of attachment figures, their likelihood of providing support during times of stress, and the self's interaction with those figures, which becomes a guide for all future close relationships. (p. 430)

internalization In moral development, the process of adopting societal standards for right action as one's own. (p. 488)

intersubjectivity The process whereby two participants who begin a task with different understandings arrive at a shared understanding. (p. 268)

invariant features Features that remain stable in a constantly changing perceptual world. (p. 168)

investment theory of creativity Sternberg and Lubart's theory, in which an individual's investment in novel projects depends on diverse cognitive, personality, motivational, and environmental resources, each of which must be present to catalyze creativity. (p. 352)

J

joint attention A state in which child and caregiver attend to the same object or event and the caregiver labels what the child sees, which contributes to language development. (p. 371)

K

kinship studies Studies comparing the characteristics of family members to estimate the importance of heredity in complex human characteristics. (p. 120)

kwashiorkor A disease caused by an unbalanced diet very low in protein, which usually strikes after weaning, between 1 and 3 years of age. Symptoms include an enlarged belly, swollen feet, hair loss, skin rash, and irritable, listless behavior. (p. 196)

L

laboratory experiment An experiment conducted in the laboratory, permitting the maximum possible control over treatment conditions. (p. 56)

language acquisition device (LAD) In Chomsky's theory, an innate system containing a universal grammar, or set of rules common to all languages, that permits children, once they have acquired sufficient vocabulary, to understand and speak in a rule-oriented fashion. (p. 360)

lanugo White, downy hair that covers the entire body of the fetus, helping the vernix stick to the skin. (p. 92)

lateralization Specialization of functions in the two hemispheres of the cerebral cortex. (p. 187)

learned helplessness The view that success is due to external factors, such as luck, while failure is due to low ability, which cannot be improved by trying hard. Distinguished from *mastery-oriented attributions.* (p. 465)

learning disability Great difficulty with one or more aspects of learning, usually reading, resulting in achievement considerably behind what would be expected on the basis of a child's IQ. (p. 646)

logical necessity A basic property of propositional thought, which specifies that the accuracy of conclusions drawn from premises rests on the rules of logic, not on real-world confirmation. (p. 258)

longitudinal design A research design in which one group of participants is studied repeatedly at different ages. Distinguished from *cross-sectional design.* (p. 60)

long-term memory In information processing, the largest storage area of the mental system, containing our permanent knowledge base. (p. 280)

M

macrosystem In ecological systems theory, cultural values, laws, customs, and resources that influence experiences and interactions at inner levels of the environment. Distinguished from *microsystem, mesosystem, exosystem,* and *chronosystem.* (p. 28)

make-believe play A type of play in which children act out everyday and imaginary activities. (p. 230)

marasmus A wasted condition of the body caused by a diet low in all essential nutrients. Usually appears in the first year of life. (p. 196)

mastery-oriented attributions Attributions that credit success to ability, which can be improved by trying hard, and that credit failure to insufficient effort. Distinguished from *learned helplessness.* (p. 465)

matching A research procedure in which participants are measured ahead of time on the factor in question, enabling investigators to assign participants with similar characteristics in equal numbers to each treatment condition in an experiment. Ensures that groups will be equivalent on factors likely to distort the results. (p. 58)

matters of personal choice Concerns that do not violate rights or others' welfare and are up to the individual. Distinguished from *moral imperatives* and *social conventions.* (p. 510)

maturation A genetically determined, naturally unfolding course of growth. (p. 12)

meiosis The process of cell division through which gametes are formed and in which the number of chromosomes in each cell is halved. (p. 75)

menarche First menstruation. (p. 203)

mental representation An internal depiction of information that the mind can manipulate, including images and concepts. (p. 227)

mesosystem In ecological systems theory, connections between children's immediate settings, or microsystems. Distinguished from *microsystem, exosystem, macrosystem,* and *chronosystem.* (p. 27)

metacognition Awareness and understanding of various aspects of thought. (p. 303)

metalinguistic awareness The ability to think about language as a system. (p. 394)

microgenetic design A research design in which investigators present children with a novel task and follow their mastery over a series of closely spaced sessions. (p. 64)

microsystem In ecological systems theory, the innermost level of the environment, consisting of activities and interaction patterns in the child's immediate surroundings. Distinguished from *mesosystem, exosystem, macrosystem,* and *chronosystem.* (p. 27)

mirror neurons Specialized cells in many areas of the cerebral cortex in primates that underlie the ability to imitate by firing identically when a primate hears or sees an action and when it carries out that action on its own. (p. 146)

mitosis The process of cell duplication, in which each new cell receives an exact copy of the original chromosomes. (p. 74)

model of strategy choice An attempt to apply an evolutionary metaphor, "natural selection," to children's mental strategies by analyzing how, when given challenging problems, children first generate and test a variety of strategies and then select the most accurate, efficient strategies, which "survive," while others become less frequent and "die off." (p. 284)

modifier genes Genes that enhance or dilute the effects of other genes. (p. 79)

moral identity An individual's endorsement of moral values, such as fairness, kindness, and generosity, as central to his or her self-concept. (p. 489)

moral imperatives Social rules and expectations that protect people's rights and welfare. Distinguished from *social conventions* and *matters of personal choice.* (p. 510)

morality of cooperation Piaget's second stage of moral development, in which children view rules as flexible, socially agreed-on principles that can be revised to suit the will of the majority. (p. 497)

moral self-regulation The ability to monitor one's own conduct, constantly adjusting it as circumstances present opportunities to violate inner standards. (p. 515)

morphology The use of grammatical markers indicating number, tense, case, person, gender, active or passive voice, and other meanings. (p. 360)

mutation A sudden but permanent change in a segment of DNA. (p. 81)

mutual exclusivity bias Children's assumption in early vocabulary growth that words refer to entirely separate, nonoverlapping categories. (p. 382)

myelination The coating of neural fibers with myelin, an insulating fatty sheath that improves the efficiency of message transfer. (p. 186)

N

natural, or **prepared, childbirth** A group of techniques aimed at reducing pain and medical intervention and making childbirth as rewarding an experience as possible. Typically includes classes that provide information about the birth process, relaxation and breathing techniques to counteract the pain of uterine contractions, and a labor coach who provides encouragement and affection. (p. 110)

natural, or **quasi-, experiment** A research design in which the investigator compares the effects of treatments that already exist in natural settings by carefully selecting groups of participants with similar characteristics. (p. 58)

naturalistic observation A research method in which the investigator goes into the natural environment and records the behavior of interest. Distinguished from *structured observation.* (p. 42)

nature–nurture controversy Disagreement among theorists over whether genetic or environmental factors are more important influences on development. (p. 8)

neglected children Children who are seldom mentioned, either positively or negatively, on self-report measures of peer acceptance. Distinguished from *popular, rejected,* and *controversial children.* (p. 618)

Neonatal Behavioral Assessment Scale (NBAS) A test developed to assess a newborn infant's behavioral status by evaluating the baby's reflexes, muscle tone, state changes, and responsiveness to physical and social stimuli. (p. 138)

neonatal mortality The number of deaths within the first month of life per 1,000 live births. (p. 118)

neo-Piagetian theory A reinterpretation of Piaget's stages within an information-processing framework. For example, Case's theory attributes change within each stage, and movement from one stage to the next, to increases in the efficiency with which children use their limited working memory capacity. (p. 283)

neurobiological methods Research methods that measure the relationship between nervous system processes and behavior to uncover the biological bases of perceptual, cognitive, and emotional responses. (p. 47)

neurons Nerve cells that store and transmit information. (p. 185)

neurotransmitters Chemicals released by neurons that cross the synapse to send messages to other neurons. (p. 185)

niche-picking A type of genetic–environmental correlation in which individuals actively choose environments that complement their heredity. (p. 123)

non-rapid-eye-movement (NREM) sleep A "regular" sleep state in which the body is almost motionless and heart rate, breathing, and brain-wave activity are slow and even. Distinguished from *rapid-eye-movement (REM) sleep.* (p. 133)

nonshared environmental influences Environmental influences that make siblings living in the same home different from one another. Distinguished from *shared environmental influences.* (p. 344)

nonsocial activity Unoccupied, onlooker behavior and solitary play. Distinguished from *parallel play, associative play,* and *cooperative play.* (p. 608)

normal distribution A bell-shaped distribution that results when individual differences are measured in large samples. Most scores cluster around the mean, or average, with progressively fewer falling toward each extreme. (p. 330)

normative approach An approach in which measures of behavior are taken on large numbers of individuals, and age-related averages are computed to represent typical development. (p. 13)

O

obesity A greater-than-20-percent increase over healthy body weight, based on body mass index, a ratio of weight to height associated with body fat. (p. 198)

object permanence The understanding that objects continue to exist when they are out of sight. (p. 229)

observer bias The tendency of observers who are aware of the purposes of a study to see and record what they expect to see rather than what participants actually do. (p. 45)

observer influence The tendency of participants in a study to behave in unnatural ways in the presence of an observer. (p. 45)

operant conditioning A form of learning in which a spontaneous behavior is followed by a stimulus that changes the probability that the behavior will occur again. (p. 141)

operations In Piaget's theory, mental representations of actions that obey logical rules. (p. 243)

ordinality Order relationships (more than and less than) between quantities. (p. 310)

organization In Piaget's theory, the internal rearrangement and linking together of schemes so that they form a strongly interconnected cognitive system. In information processing, a memory strategy that involves grouping related information to improve recall. (pp. 227, 292)

overextension An early vocabulary error in which a word is applied to a wider collection of objects and events than is appropriate. Distinguished from *underextension.* (p. 380)

overregularization Extension of regular morphological rules to words that are exceptions. (p. 386)

P

parallel play A form of limited social participation in which a child plays near other children with similar materials but does not try to influence their behavior. Distinguished from *nonsocial activity, associative play,* and *cooperative play.* (p. 608)

partial fetal alcohol syndrome (p-FAS) A form of fetal alcohol spectrum disorder characterized by facial abnormalities and brain injury but less severe than fetal alcohol syndrome; usually seen in children whose mothers drank alcohol in smaller quantities during pregnancy. Distinguished from *fetal alcohol syndrome (FAS)* and *alcohol-related neurodevelopmental disorder (ARND).* (p. 99)

peer acceptance Likability, or the extent to which a child is viewed by a group of agemates, such as classmates, as a worthy social partner. (p. 618)

peer group A collective of peers who generate unique values and standards for behavior and a social structure of leaders and followers. (p. 622)

peer victimization A destructive form of peer interaction in which certain children become frequent targets of verbal and physical attacks or other forms of abuse. (p. 621)

perceptual narrowing effect Perceptual sensitivity that becomes increasingly attuned with age to information most often encountered. (p. 156)

permissive child-rearing style A child-rearing style that is high in acceptance but overindulging or inattentive, low in control, and lenient rather than appropriate in autonomy granting. Distinguished from *authoritative, authoritarian,* and *uninvolved child-rearing styles.* (p. 575)

person perception The way individuals size up the attributes of people with whom they are familiar. (p. 476)

personal fable Adolescents' inflated opinion of their own importance—the belief that they are special and unique and that others cannot possibly understand their thoughts and feelings. (p. 255)

perspective taking The capacity to imagine what others may be thinking and feeling. (p. 452)

phenotype An individual's directly observable physical and behavioral characteristics, which are determined by both genetic and environmental factors. Distinguished from *genotype.* (p. 73)

phonemes The smallest sound units that signal a change in meaning. (p. 368)

phonics approach An approach to beginning reading instruction that emphasizes coaching children on phonics—the basic rules for translating written symbols into sounds—before exposing them to complex reading material. Distinguished from *whole-language approach.* (p. 309)

phonological awareness The ability to reflect on and manipulate the sound structure of spoken language, as indicated by sensitivity to changes in sounds within words, to rhyming, and to incorrect pronunciation—a strong predictor of emergent literacy knowledge. (p. 308)

phonological store A special part of short-term memory that permits retention of speech-based information and, thus, supports early vocabulary development. (p. 381)

phonology The component of language consisting of the rules governing the structure and sequence of speech sounds. (p. 360)

physical aggression A form of aggression that harms others through physical injury to themselves or their property. Distinguished from *verbal aggression* and *relational aggression.* (p. 517)

pincer grasp The well-coordinated grasp that emerges at the end of the first year, involving thumb and index finger opposition. (p. 151)

pituitary gland A gland located at the base of the brain that releases hormones affecting physical growth. (p. 181)

placenta The organ that permits exchange of nutrients and waste products between the bloodstreams of the mother and the embryo, while also preventing the mother's and embryo's blood from mixing directly. (p. 89)

planning Thinking out a sequence of acts ahead of time and allocating attention accordingly to reach a goal. (p. 289)

plasticity Openness to change in response to influential experiences. (p. 9)

polygenic inheritance A pattern of inheritance in which many genes determine a characteristic that varies on a continuum among people. (p. 81)

popular-antisocial children A subtype of popular children who are admired for their socially adept yet belligerent behavior. Includes "tough" boys who are athletically skilled, aggressive, and poor students as well as relationally aggressive children who enhance their own status by ignoring, excluding, and spreading rumors about other children. Distinguished from *popular-prosocial children.* (p. 619)

popular children Children who get many positive votes on self-report measures of peer acceptance, indicating that they are well-liked. Distinguished from *rejected, controversial,* and *neglected children.* (p. 618)

popular-prosocial children A subtype of popular children who combine academic and social competence. Distinguished from *popular-antisocial children.* (p. 619)

postconventional level Kohlberg's highest level of moral development, in which individuals define morality in terms of abstract principles and values that apply to all situations and societies. (p. 501)

practical intelligence Mental abilities apparent in the real world but not in testing situations. (p. 332)

practice effects Improvement in research participants' performance with repeated testing, resulting from better test-taking skills and increased familiarity with the test. (p. 62)

pragmatics The component of language consisting of the rules for engaging in appropriate and effective communication. (p. 360)

preconventional level Kohlberg's first level of moral development, in which morality is externally controlled—based on rewards, punishments, and the power of authority figures. (p. 500)

prefrontal cortex The region of the cerebral cortex, lying in front of areas controlling body movement, that is responsible for thought—in particular, for consciousness, attention, inhibition of impulses, integration of information, and use of memory, reasoning, planning, and problem-solving strategies. (p. 186)

prenatal diagnostic methods Medical procedures that permit detection of developmental problems before birth. (p. 84)

preoperational stage Piaget's second stage, extending from about 2 to 7 years of age, in which children undergo an extraordinary increase in representational, or symbolic, activity, although thought is not yet logical. (p. 239)

prereaching The poorly coordinated, primitive reaching movements of newborn babies. (p. 150)

preterm infants Infants born several weeks or more before their due date. (p. 114)

primary sexual characteristics Physical features of the reproductive organs—ovaries, uterus, and vagina in females; penis, scrotum, and testes in males. Distinguished from *secondary sexual characteristics*. (p. 203)

private speech Self-directed speech that children use to guide their own thinking and behavior. (p. 267)

proactive aggression A type of aggression in which children act to fulfill a need or desire—obtain an object, privilege, space, or social reward—and unemotionally attack a person to achieve their goal. Also called instrumental aggression. Distinguished from *reactive aggression.* (p. 517)

problem-centered coping A general strategy for managing emotion in which the individual appraises the situation as changeable, identifies the difficulty, and decides what to do about it. Distinguished from *emotion-centered coping.* (p. 412)

production In language development, the words and word combinations that children use. Distinguished from *comprehension.* (p. 376)

production deficiency Failure to produce a mental strategy when one could be helpful. Distinguished from *control deficiency, utilization deficiency,* and *effective strategy use.* (p. 288)

programmed cell death Death of many surrounding neurons as neural fibers and their synapses increase rapidly, which makes space for these connective structures. (p. 185)

Project Head Start A U.S. federal early intervention program for economically disadvantaged preschoolers that provides children with a year or two of preschool education, along with nutritional and health services, and encourages parent involvement in program planning and children's learning and development. (p. 347)

propositional thought A type of formal operational reasoning involving the ability to evaluate the logic of propositions (verbal statements) without referring to real-world circumstances. (p. 254)

prosocial, or **altruistic, behavior** Actions that benefit another person without any expected reward for the self. (p. 417)

protection from harm The right of research participants to be protected from risks to their safety or welfare. (p. 67)

protodeclarative A preverbal communicative gesture in which the baby points to, touches, or holds up an object while looking at others to make sure they notice. Distinguished from *protoimperative.* (p. 371)

protoimperative A preverbal communicative gesture in which the baby gets another person to do something by reaching, pointing, and often making sounds at the same time. Distinguished from *protodeclarative.* (p. 371)

proximodistal trend An organized pattern of physical growth and motor control that proceeds from the center of the body outward. Distinguished from *cephalocaudal trend.* (p. 176)

psychoanalytic perspective An approach to personality development introduced by Freud, which assumes that children move through a series of stages in which they confront conflicts between biological drives and social expectations. How these conflicts are resolved determines the person's ability to learn, to get along with others, and to cope with anxiety. (p. 15)

psychological control Parental behaviors that intrude on and manipulate children's verbal expressions, individuality, and attachments to parents. (p. 574)

psychometric approach An approach to cognitive development that focuses on outcomes and results and is the basis for intelligence tests designed to assess mental abilities. (p. 319)

psychosexual theory Freud's theory of development, which emphasizes that how parents manage their child's sexual and aggressive drives in the first few years is crucial for healthy personality development. (p. 15)

psychosocial dwarfism A growth disorder, usually appearing between 2 and 15 years of age, caused by extreme emotional deprivation. Typical characteristics include decreased growth hormone secretion, very short stature, immature skeletal age, and serious adjustment problems, which help distinguish it from typical shortness. (p. 202)

psychosocial theory Erikson's theory, which emphasizes that in each Freudian stage, individuals not only develop a unique personality but also acquire attitudes and skills that help them become active, contributing members of their society. (p. 15)

puberty Biological changes at adolescence that lead to an adult-sized body and sexual maturity. (p. 203)

public policy Laws and government programs designed to improve current conditions. (p. 33)

punishment In operant conditioning, removal of a desirable stimulus or presentation of an unpleasant stimulus, either of which decreases the occurrence of a response. (p. 141)

R

random assignment Assignment of participants in an experiment to treatment conditions using an unbiased procedure, such as drawing numbers out of a hat or flipping a coin, to increase the chances that participants' characteristics will be equally distributed across treatment groups. (p. 57)

rapid-eye-movement (REM) sleep An "irregular" sleep state in which electrical brain-wave activity is similar to that of the waking state; eyes dart beneath the lids; heart rate, blood pressure, and breathing are uneven; and slight body movements occur. Distinguished from *non-rapid-eye-movement (NREM) sleep.* (p. 133)

reactive aggression An angry, defensive response to a provocation or a blocked goal; intended to hurt another person. Also called hostile aggression. Distinguished from *proactive aggression.* (p. 517)

realism In Piaget's heteronomous stage of moral development, the child's tendency to view rules, like other mental phenomena, as fixed external features of reality. (p. 487)

recall The form of memory retrieval that involves generating a mental representation of an absent stimulus. Distinguished from *recognition.* (p. 294)

recasts Adult responses that restructure children's grammatically inaccurate speech into correct form. (p. 389)

reciprocal teaching A teaching method in which a teacher and two to four students form a cooperative group and take turns leading dialogues, creating a zone of proximal development in which children scaffold one another's progress. (p. 271)

recognition The simplest form of memory retrieval, which involves noticing that a stimulus is identical or similar to one previously experienced. Distinguished from *recall.* (p. 294)

reconstruction The type of memory that involves recoding information while it is in the mental system or being retrieved. (p. 295)

recovery Following habituation, an increase in responsiveness to a new stimulus. (p. 142)

recursive thought A form of perspective taking that requires the ability to view a situation from at least two perspectives—that is, to reason simultaneously about what two or more people are thinking. (p. 453)

referential communication skills The ability to produce clear verbal messages and to recognize when the meaning of others' messages is unclear. (p. 391)

referential style A style of early language learning in which toddlers use language mainly to label objects. Distinguished from *expressive style.* (p. 378)

reflex An inborn, automatic response to a particular form of stimulation. (p. 130)

rehearsal A memory strategy that involves repeating information to oneself. (p. 292)

reinforcer In operant conditioning, a stimulus that increases the occurrence of a response. (p. 141)

rejected-aggressive children A subtype of rejected children who show high rates of conflict, physical and relational aggression, and hyperactive, inattentive, and impulsive behavior. Distinguished from *rejected-withdrawn children.* (p. 619)

rejected children Children who get many negative votes on self-report measures of peer acceptance, indicating that they are actively disliked. Distinguished from *popular, controversial,* and *neglected children.* (p. 618)

rejected-withdrawn children A subtype of rejected children who are passive, socially awkward, and overwhelmed by social anxiety. Distinguished from *rejected-aggressive children.* (p. 619)

relational aggression A form of aggression that damages a peer's relationships through social exclusion, malicious gossip, or friendship manipulation. Distinguished from *physical aggression* and *verbal aggression.* (p. 518)

reliability The consistency, or repeatability, of measures of behavior. (p. 54)

remembered self The child's life-story narrative, or autobiographical memory, constructed from conversations with adults about the past. (p. 450)

resilience The ability to adapt effectively in the face of threats to development. (p. 10)

resistant attachment The quality of insecure attachment characterizing infants who seek closeness to the parent before her departure, are usually distressed when she leaves, and combine clinginess with angry, resistive behavior when she returns. Distinguished from *secure, avoidant,* and *disorganized/disoriented attachment.* (p. 431)

reticular formation A structure in the brain stem that maintains alertness and consciousness. (p. 190)

reversibility The ability to go through a series of steps in a problem and then mentally reverse direction, returning to the starting point. In Piaget's theory, part of every logical operation. (p. 245)

Rh factor incompatibility A condition that arises when the Rh protein is present in the fetus's blood but not in the mother's, causing the mother to build up antibodies. If these enter the fetus's system, they destroy red blood cells, reducing the oxygen supply to organs and tissues. (p. 113)

risks-versus-benefits ratio A comparison of the costs of a research study to participants in terms of inconvenience and possible psychological or physical injury against the study's value for advancing knowledge and improving conditions of life. Used in assessing the ethics of research. (p. 67)

rough-and-tumble play A form of peer interaction involving friendly chasing and play-fighting that, in our evolutionary past, may have been important for the development of fighting skill. (p. 610)

S

scaffolding Adjusting the support offered during a teaching session to fit the child's current level of performance. As competence increases, the adult gradually and sensitively withdraws support, turning responsibility over to the child. (p. 268)

scale errors Toddlers' attempts to do things that their body size makes impossible because they lack an objective understanding of their own body dimensions. (p. 449)

schemes In Piaget's theory, specific psychological structures, or organized ways of making sense of experience, that change with age. (p. 226)

scripts General descriptions of what occurs and when it occurs in a particular situation, used to organize, interpret, and predict repeated events. (p. 298)

secondary sexual characteristics Features visible on the outside of the body that do not involve the reproductive organs but serve as signs of sexual maturity, including breast development in females and the appearance of underarm and pubic hair in both sexes. Distinguished from *primary sexual characteristics.* (p. 203)

secular trends in physical growth Changes in body size and rate of growth from one generation to the next. (p. 184)

secure attachment The attachment pattern characterizing infants who use the parent as a secure base from which to explore and who are easily comforted by the parent on being reunited after a separation. Distinguished from *avoidant, resistant,* and *disorganized/disoriented attachment.* (p. 430)

secure base The baby's use of the familiar caregiver as the point from which to explore, venturing into the environment and then returning for emotional support. (p. 408)

selective attrition Selective loss of participants during an investigation, resulting in a biased sample. (p. 62)

self-care children School-age children who regularly look after themselves for some period of time during after-school hours. (p. 597)

self-concept The set of attributes, abilities, attitudes, and values that an individual believes defines who he or she is. (p. 456)

self-conscious emotions Emotions—such as shame, embarrassment, guilt, envy, and pride—that involve injury to or enhancement of the sense of self. (p. 408)

self-esteem The aspect of self-concept that involves judgments about one's own worth and the feelings associated with those judgments. (p. 461)

self-recognition Identification of the self as a physically unique being, distinct from other people and objects. (p. 449)

semantic bootstrapping In language development, children's reliance on semantics, or word meanings, to figure out sentence structure. (p. 389)

semantic memory The vast, taxonomically organized and hierarchically structured general knowledge system, consisting of concepts, language meanings, facts, and rules. (p. 296)

semantics The component of language that involves vocabulary—the way underlying concepts are expressed in words and word combinations. (p. 360)

sensitive caregiving Caregiving that involves responding promptly, consistently, and appropriately to infants and holding them tenderly and carefully. (p. 434)

sensitive period A time that is optimal for certain capacities to emerge and in which the individual is especially responsive to environmental influences. (p. 24)

sensorimotor stage Piaget's first stage, spanning the first two years of life, in which infants and toddlers "think" with their eyes, ears, hands, and other sensorimotor equipment but cannot yet carry out many activities mentally. (p. 228)

sensory register The part of the information-processing system in which sights and sounds are represented directly but stored only momentarily before they either decay or are transferred to the short-term memory store. (p. 278)

separation anxiety An infant's distressed reaction to the departure of the trusted caregiver. (p. 429)

sequential designs Research designs in which several similar cross-sectional or longitudinal investigations, or sequences, are conducted at varying times. May permit both longitudinal and cross-sectional comparisons and detection of cohort effects. (p. 63)

seriation The ability to order items along a quantitative dimension, such as length or weight. (p. 250)

sex chromosomes The twenty-third pair of chromosomes, called XX in females and XY in males, which determines the sex of the child. (p. 76)

shading A conversational strategy in which a speaker initiates a change of topic gradually by modifying the focus of discussion. (p. 390)

shape bias In early language development, children's tendency to rely heavily on shape as a distinguishing property when learning names for objects. (p. 382)

shape constancy Perception of an object's shape as stable, despite changes in the shape projected on the retina. (p. 165)

shared environmental influences Influences that pervade the general atmosphere of the home and, therefore, similarly affect siblings living in it. Distinguished from *nonshared environmental influences.* (p. 344)

short-term memory store The part of the information-processing system in which attended-to information is briefly retained so we can actively "work" on it to reach our goals. (p. 278)

size constancy Perception of an object's size as stable, despite changes in the size of its retinal image. (p. 164)

skeletal age An estimate of physical maturity based on development of the bones of the body. (p. 178)

slow-to-warm-up child A child whose temperament is characterized by inactivity; mild, low-key reactions to environmental stimuli; negative mood; and slow adjustment to new experiences. Distinguished from *easy child* and *difficult child.* (p. 420)

small-for-date infants Infants whose birth weight is below their expected weight considering the length of the pregnancy. (p. 114)

social cognition Thinking about characteristics of the self and of other people. (p. 447)

social comparisons Evaluations of one's own appearance, abilities, and behavior in relation to those of others. (p. 458)

social-constructivist classroom A classroom grounded in Vygotsky's sociocultural theory, in which children participate in a wide range of challenging activities with teachers and peers, with whom they jointly construct understandings. Distinguished from *traditional classroom* and *constructivist classroom.* (p. 640)

social conventions Customs, such as table manners and rituals of social interaction, that are determined solely by consensus. Distinguished from *moral imperatives* and *matters of personal choice.* (p. 510)

social learning theory A theory that emphasizes the role of modeling, otherwise known as imitation or observational learning, in the development of behavior. (p. 18)

social policy Any planned set of actions by a group, institution, or governing body directed at attaining a social goal. (p. 33)

social problem solving Generating and applying strategies that prevent or resolve disagreements, resulting in outcomes that are both acceptable to others and beneficial to the self. (p. 480)

social referencing Actively seeking emotional information from a trusted person in an uncertain situation. (p. 414)

social smile The smile evoked by the stimulus of the human face. First appears between 6 and 10 weeks. (p. 406)

social systems perspective A view of the family as a complex set of interacting relationships influenced by the larger social context. (p. 568)

sociocultural theory Vygotsky's theory, in which children acquire the ways of thinking and behaving that make up a community's culture through social interaction—in particular, cooperative dialogues with more knowledgeable members of society. (p. 25)

sociodramatic play The make-believe play with others that is under way around age 2 and increases rapidly in complexity during early childhood. (p. 240)

socioeconomic status (SES) A measure of a family's social position and economic well-being that combines three related variables: years of education, the prestige of one's job and the skill it requires, and income. (p. 334)

specific intelligence In Spearman's theory, a mental ability that is unique to a task. Distinguished from *general intelligence,* or *"g."* (p. 321)

speech registers Language adaptations to social expectations. (p. 393)

spermarche First ejaculation of seminal fluid. (p. 204)

stage A qualitative change in thinking, feeling, and behaving that characterizes a specific period of development. (p. 8)

standardization The practice of giving a newly constructed test to a large, representative sample of individuals and using the results as the standard for interpreting individual scores. (p. 330)

Stanford-Binet Intelligence Scales, Fifth Edition An individually administered intelligence test, appropriate for individuals age 2 to adulthood, that is the modern descendant of Alfred Binet's first successful test for children. Measures general intelligence and five intellectual factors: fluid reasoning, quantitative reasoning, knowledge, visual-spatial processing, and working memory. (p. 327)

states of arousal Different degrees of sleep and wakefulness. (p. 132)

statistical learning capacity The capacity to analyze the speech stream for repeatedly occurring sound sequences, through which infants acquire a stock of speech structures for which they will later learn meanings. (p. 157)

stereotype threat The fear of being judged on the basis of a negative stereotype, which can trigger anxiety that interferes with performance. (p. 341)

Strange Situation A laboratory technique for assessing the quality of infant–caregiver attachment between 1 and 2 years of age by observing the baby's responses to eight short episodes, in which brief separations from and reunions with the caregiver occur in an unfamiliar playroom. (p. 430)

stranger anxiety Expression of fear in response to unfamiliar adults, which appears in many babies in the second half of the first year. (p. 407)

structured interview An interview method in which each participant is asked the same questions in the same way. (p. 47)

structured observation A method in which the researcher sets up a laboratory situation that evokes the behavior of interest so that every participant has an equal opportunity to display the response. Distinguished from *naturalistic observation.* (p. 44)

sudden infant death syndrome (SIDS) The unexpected death, usually during the night, of an infant under 1 year of age that remains unexplained after thorough investigation. (p. 136)

sympathy Feelings of concern or sorrow for another's plight. (p. 417)

synapses The gaps between neurons, across which chemical messages are sent. (p. 185)

synaptic pruning Loss of synapses by seldom-stimulated neurons, thereby returning them to an uncommitted state so they can support future development. (p. 185)

syntactic bootstrapping In language development, children's discovery of word meanings by observing how words are used in syntax, or the structure of sentences. (p. 382)

syntax The rules by which words are arranged into sentences. (p. 360)

T

talent Outstanding performance in one or a few related fields. (p. 353)

telegraphic speech Young children's two-word utterances that, like a telegram, focus on high-content words, omitting smaller, less important ones. (p. 384)

temperament Early-appearing, stable individual differences in reactivity (quickness and intensity of emotional arousal, attention, and motor action) and self-regulation (strategies that modify reactivity). (p. 418)

teratogen Any environmental agent that causes damage during the prenatal period. (p. 95)

theory An orderly, integrated set of statements that describes, explains, and predicts behavior. (p. 6)

theory of mind A coherent understanding of people as mental beings, which children revise as they encounter new evidence. (p. 303)

theory of multiple intelligences Gardner's theory, which proposes at least eight independent intelligences, defined in terms of distinct sets of processing operations applied in culturally valued activities: linguistic, logico-mathematical, musical, spatial, bodily-kinesthetic, naturalist, interpersonal, and intrapersonal. (p. 325)

theory theory A theory that assumes that children draw on innate concepts to form naïve theories, or explanations of events, that differ among core domains of thought. Then they test their theory against experience, revising it when it cannot adequately account for new information. (p. 264)

three-stratum theory of intelligence Carroll's factor-analytic theory, which represents the structure of intelligence in three tiers, with *g* at the top; a second tier of biologically based broad abilities; and a third tier of specific behaviors. The most comprehensive factor-analytic classification of mental abilities to date. (p. 322)

thyroid-stimulating hormone (TSH) A pituitary hormone that stimulates the thyroid gland to release thyroxine, which is necessary for brain development and for growth hormone to have its full impact on body size. (p. 183)

time out A form of mild punishment in which children are removed from the immediate setting until they are ready to act appropriately. (p. 493)

time sampling A form of systematic observation in which the researcher records whether certain behaviors occur during a sample of short intervals. (p. 45)

traditional classroom A classroom in which the teacher is the sole authority for knowledge, rules, and decision making and students are relatively passive learners who are evaluated in relation to a uniform set of standards. Distinguished from *constructivist classroom* and *social-constructivist classroom.* (p. 638)

transitive inference The ability to seriate, or arrange items along a quantitative dimension, mentally. (p. 250)

triarchic theory of successful intelligence Sternberg's theory, which states that intelligent behavior involves balancing analytical intelligence, creative intelligence, and practical intelligence to achieve success in life, according to one's personal goals and the requirements of one's cultural community. (p. 323)

turnabout A conversational strategy in which the speaker, after commenting on what has just been said, also adds a request to get the partner to respond again. (p. 390)

U

ulnar grasp The clumsy grasp of the young infant, in which the fingers close against the palm. (p. 151)

umbilical cord The long cord connecting the prenatal organism to the placenta that delivers nutrients and removes waste products. (p. 89)

unconditioned response (UCR) In classical conditioning, a reflexive response that is produced by an unconditioned stimulus (UCS). (p. 140)

unconditioned stimulus (UCS) In classical conditioning, a stimulus that consistently produces a reflexive, or unconditioned, response (UCR). (p. 140)

underextension An early vocabulary error in which a word is applied too narrowly, to a smaller number of objects or events than is appropriate. Distinguished from *overextension.* (p. 379)

uninhibited, or **sociable, child** A child who tends to display positive emotion to and approach novel stimuli. Distinguished from *inhibited,* or *shy, child.* (p. 421)

uninvolved child-rearing style A child-rearing style that combines low acceptance and involvement with little behavioral control and general indifference to issues of autonomy. Distinguished from *authoritarian, authoritative,* and *permissive child-rearing styles.* (p. 575)

universal grammar In Chomsky's theory of language development, a built-in storehouse of grammatical rules common to all human languages. (p. 361)

utilization deficiency Failure to improve performance despite executing a mental strategy consistently. Distinguished from *production deficiency, control deficiency,* and *effective strategy use.* (p. 289)

V

validity The extent to which a research method accurately measures characteristics that the investigator set out to measure. (p. 54)

velocity curve A growth curve that plots the average amount of growth at each yearly interval for a sample of children, revealing the exact timing of growth spurts. Distinguished from *distance curve.* (p. 176)

verbal aggression A form of reactive aggression that harms others through threats of physical aggression, name-calling, or hostile teasing. Distinguished from *physical aggression* and *relational aggression.* (p. 518)

vernix A white, cheeselike substance covering the fetus, preventing the skin from chapping due to constant exposure to amniotic fluid. (p. 92)

video deficit effect In toddlers, poorer performance on a task after watching a video than a live demonstration. (p. 237)

violation-of-expectation method A method in which researchers show babies an expected event (one that follows physical laws) and an unexpected event (a variation of the first event that violates physical laws). Heightened attention to the unexpected event suggests that the infant is "surprised" by a deviation from physical reality and, therefore, is aware of that aspect of the physical world. (p. 230)

visual acuity Fineness of visual discrimination. (p. 159)

visual cliff An apparatus used to study depth perception in infants, consisting of a Plexiglas-covered table with a central platform, from which babies are encouraged to crawl. Checkerboard patterns placed at different distances beneath the glass create the appearance of a shallow and a deep side. (p. 159)

W

Wechsler Intelligence Scale for Children–IV (WISC–IV) An individually administered intelligence test, appropriate for ages 6 through 16, that measures general intelligence and four broad intellectual factors: verbal reasoning, perceptual reasoning, working memory, and processing speed. (p. 328)

Wernicke's area A language structure located in the left temporal lobe of the cerebral cortex that plays a role in comprehending word meaning. (p. 363)

whole-language approach An approach to beginning reading instruction in which, from the start, children are exposed to text in its complete form, using reading materials that are whole and meaningful to promote appreciation of the communicative function of written language. Distinguished from *phonics approach.* (p. 309)

working memory The number of items that can be briefly held in mind while also engaging in some effort to monitor or manipulate those items. A contemporary view of the short-term memory store. (p. 279)

X

X-linked inheritance A pattern of inheritance in which a recessive gene is carried on the X chromosome, so that males are more likely than females to be affected. (p. 80)

Z

zone of proximal development In Vygotsky's theory, a range of tasks too difficult for the child to do alone but possible with the help of adults and more skilled peers. (p. 267)

zygote The newly fertilized cell formed by the union of sperm and ovum at conception. (p. 75)

9 Reasons why the ninth edition of Laura Berk's *Child Development* continues to be *the* cutting-edge standard for child development texts:

1 *Thoroughly Engaging Writing Style*

Laura Berk makes the study of child development both involving and pleasurable for students. *Child Development* is written in an engaging, personal style—one that is highly accessible—and contains real-life human-interest stories. The author encourages students to relate what they read to their own lives.

> **Berk's *Child Development* is about as good as an undergraduate textbook can get. It is lively, readable, and engaging.**
>
> **—Scott P. Johnson, *UCLA***

2 *Appealing and Meaningful Applications*

Child Development's practical applications show students how their learning relates to real-world situations. Applications are relevant to students pursuing a variety of fields, including psychology, education, sociology, anthropology, family studies, social services, and health sciences. (See Features at a Glance, page v.)

3 *Exceptional Integration of Culture and Diversity*

Multicultural and cross-cultural material is presented not only in the text's research and in many positive and diverse examples, but also through rich photos, figures, and children's art, which enhance student interest and understanding.

> **This is the best text I have ever read with respect to appropriate integration of cross-cultural material without it appearing as tokenism.**
>
> **—Doug Symons, *Acadia University***

4 *Unparalleled Breadth and Depth of Research*

Child Development is well known for its up-to-date and comprehensive research coverage, presented with clarity and ease, making the study of child development current, relevant, and enjoyable for students.

> **If I were to tell you the one reason I keep coming back to this textbook year after year, it is because it has the best, most up-to-date, and most comprehensive research coverage.**
>
> **—Cecilia Wainryb, *University of Utah***

5 New and Enhanced Material in Each Chapter

Added and revised material reflects major changes and discoveries in the field. This edition includes over 1,400 new reference citations. (A list of new material can be found in the Preface for Instructors.)

6 Beautiful Artwork, Graphics, and Photographs

Visually stunning, the art, graphics, and photos effectively illustrate major points and enhance student interest and understanding.

7 Outstanding Pedagogical Features

Outstanding pedagogical features support students' mastery of the material.

Chapter Introductions

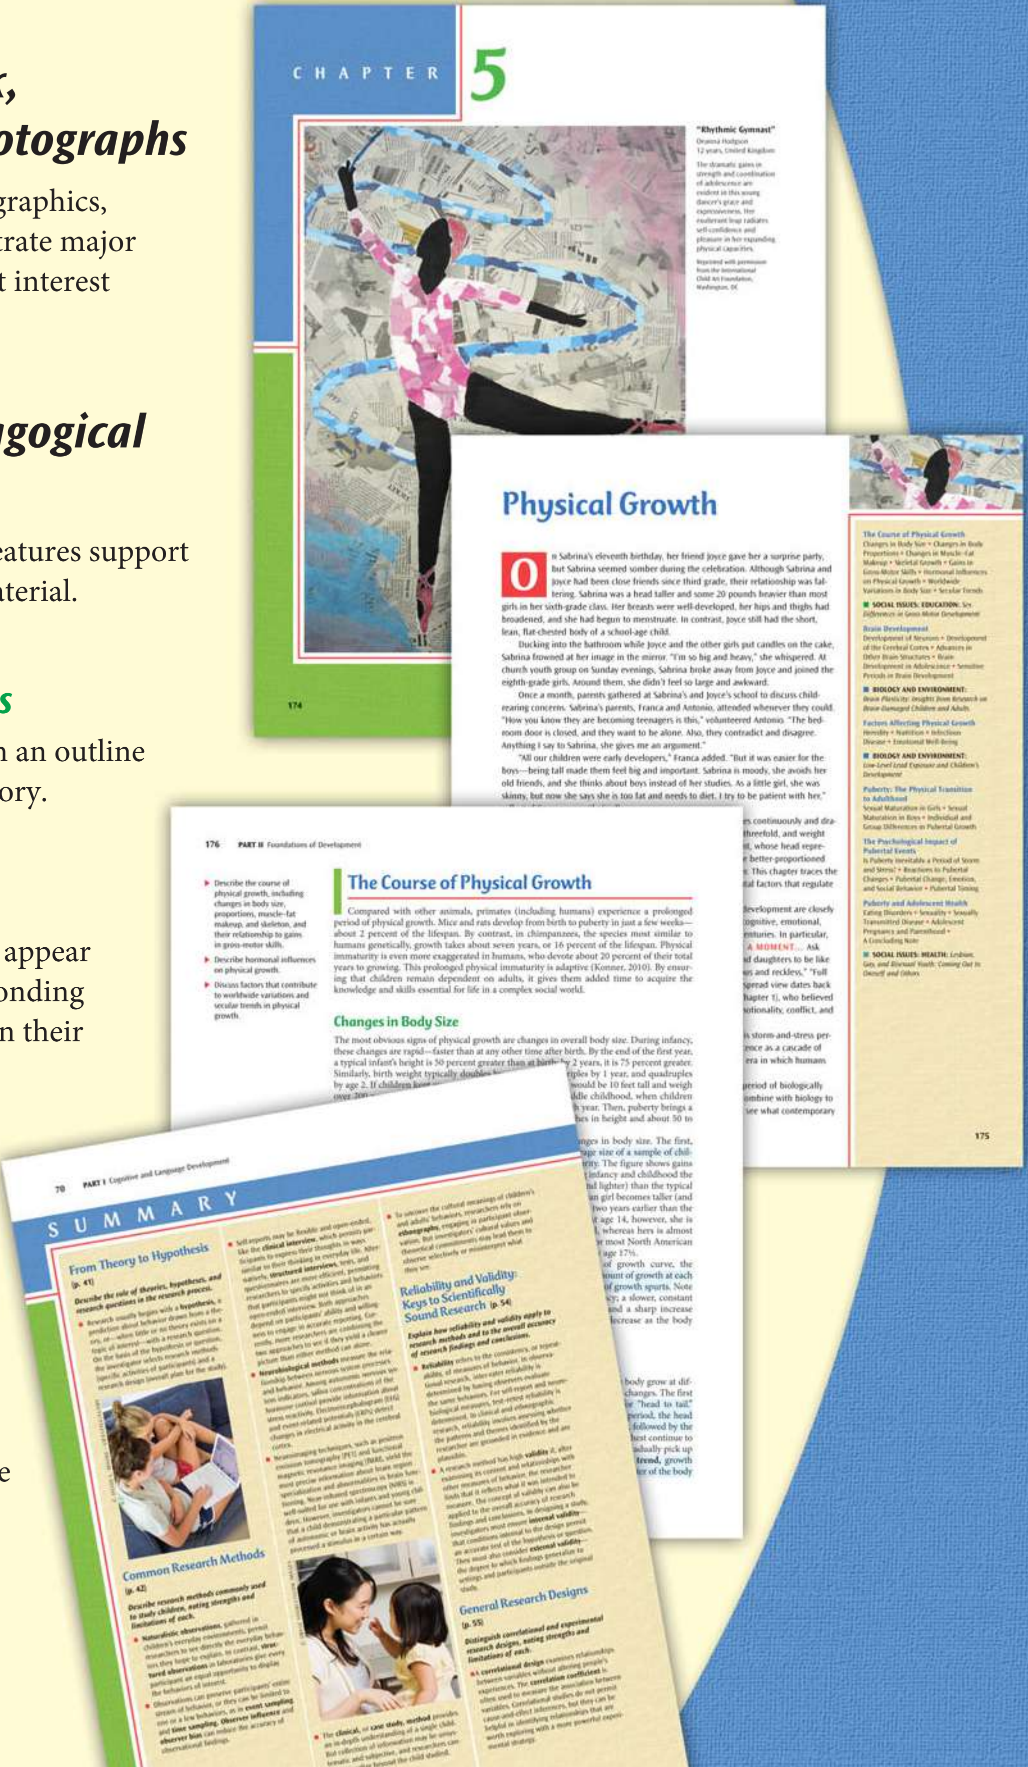
Chapter openers begin with an outline and an engaging real-life story.

Learning Objectives

NEW! Learning objectives appear at the start of their corresponding sections to guide students in their reading.

End-of-Chapter Summaries

Chapter summaries are organized by learning objectives, encouraging active study. They also include bolded key terms, which help students acquire and master the vocabulary of the field.



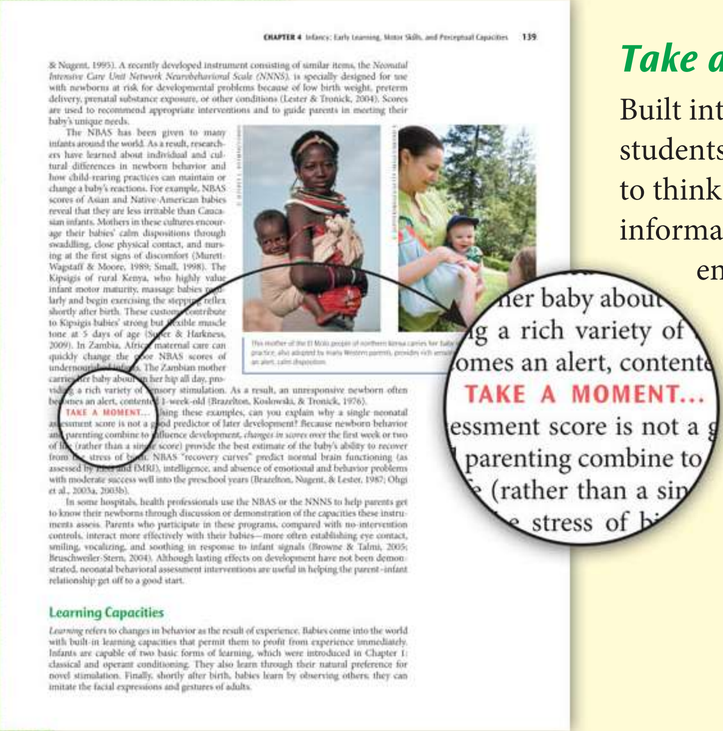
CHAPTER 5

Physical Growth

The Course of Physical Growth

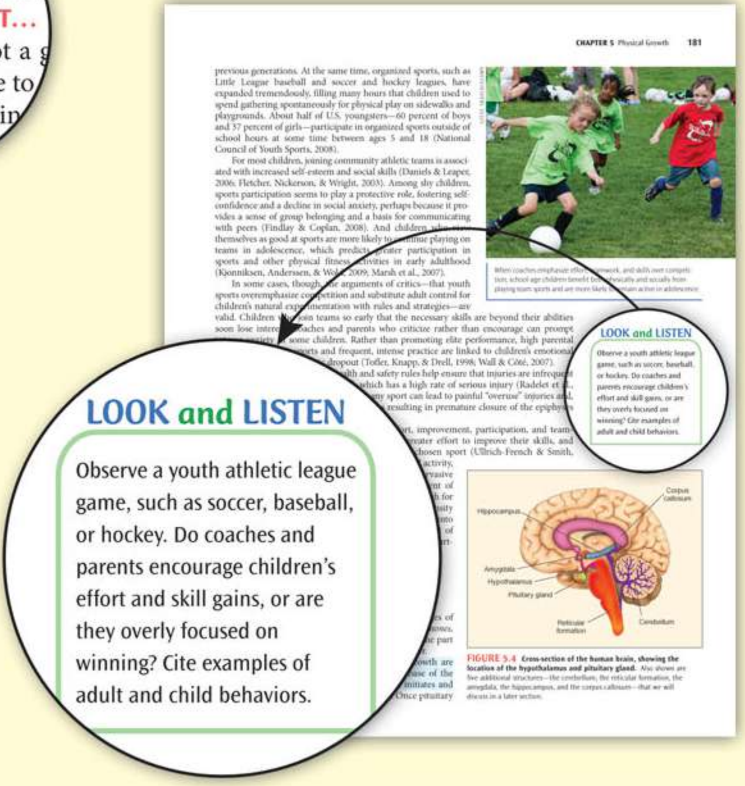
Changes in Body Size

SUMMARY



Take a Moment…

Built into the text narrative, this feature engages students by asking them to "take a moment" to think about an important point, integrate information on children's development, or engage in an exercise or an application to clarify a challenging concept.



LOOK and LISTEN

Observe a youth athletic league game, such as soccer, baseball, or hockey. Do coaches and parents encourage children's effort and skill gains, or are they overly focused on winning? Cite examples of adult and child behaviors.

Look and Listen

This **NEW** active-learning feature asks students to observe what real children say and do, speak with or observe parents and teachers, and inquire into community programs and practices that influence children.

Ask Yourself Questions

Review questions help students recall and comprehend information they have just read.

Connect questions help students build an image of the whole child by integrating what they have learned across age periods and domains of development.

Apply questions encourage the application of knowledge to controversial issues and problems faced by children, parents, and professionals who work with them.

Reflect questions help make the study of child development personally meaningful by asking students to reflect on their own development and life experiences. Each question is answered on the text's MyDevelopmentLab website.

CHAPTER 7 Cognitive Development: An Information-Processing Perspective 293

SOCIAL ISSUES: EDUCATION

Media Multitasking Disrupts Learning

442 PART IV Personality and Social Development

SOCIAL ISSUES: HEALTH

Does Child Care Threaten Infant Attachment Security and Later Adjustment?

CHAPTER 3 Biological Foundations, Prenatal Development, and Birth 125

BIOLOGY and ENVIRONMENT

A Case of Epigenesis: Smoking During Pregnancy Alters Gene Expression

CHAPTER 2 Research Strategies 53

CULTURAL INFLUENCES

Immigrant Youths: Adapting to a New Land

Feature Boxes

See page v for a complete listing of feature boxes.

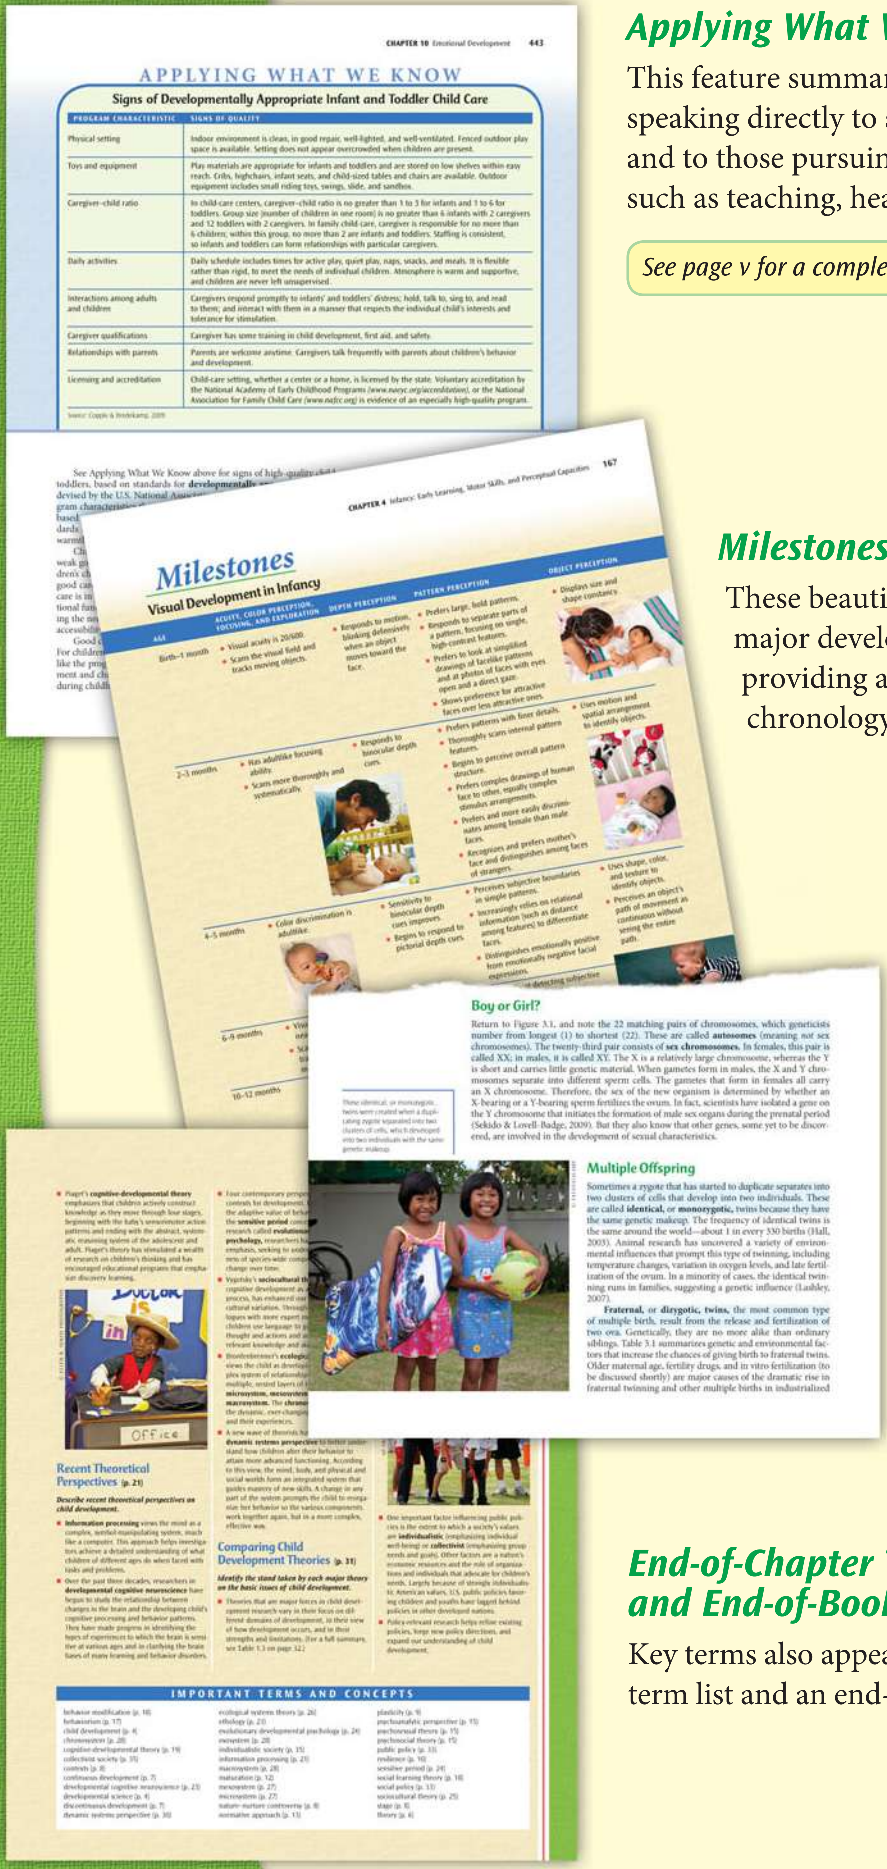
Social Issues boxes discuss the impact of social conditions on children and emphasize the need for sensitive social policies to ensure their well-being:

NEW! Social Issues: Education boxes focus on home, school, and community influences on children's learning. Examples include *Baby Learning from TV and Video: The Video Deficit Effect; Media Multitasking Disrupts Learning; The Head Start REDI Program: Strengthening School Readiness in Economically Disadvantaged Preschoolers;* and *Magnet Schools: Equal Access to High-Quality Education.*

NEW! Social Issues: Health boxes address values and practices relevant to children's physical and mental health. Examples include *Family Chaos Undermines Children's Well-Being; A Cross-National Perspective on Health Care and Other Policies for Parents and Newborn Babies; Does Child Care Threaten Infant Attachment Security and Later Adjustment?;* and *Adolescent Substance Use and Abuse.*

Biology and Environment boxes highlight the growing attention to the complex, bidirectional relationship between biology and environment. Examples include *A Case of Epigenesis: Smoking During Pregnancy Alters Gene Expression; Prenatal Iron Deficiency and Memory Impairments in Infants of Diabetic Mothers: Findings of ERP Research; Children with Attention-Deficit Hyperactivity Disorder;* and *"Mindblindness" and Autism.*

Cultural Influences boxes deepen the attention to culture threaded throughout the text and accentuate both cross-cultural and multicultural variations in child development—for example, *Immigrant Youths: Adapting to a New Land; Cultural Variation in Infant Sleeping Arrangements; Identity Development among Ethnic Minority Adolescents;* and *Impact of Ethnic and Political Violence on Children.*



Applying What We Know Tables

This feature summarizes research-based applications, speaking directly to students as parents or future parents and to those pursuing different careers or areas of study, such as teaching, health care, counseling, or social work.

See page v for a complete listing of Applying What We Know tables.

CHAPTER 10 Emotional Development 443

APPLYING WHAT WE KNOW

Signs of Developmentally Appropriate Infant and Toddler Child Care

PROGRAM CHARACTERISTIC	SIGNS OF QUALITY
Physical setting	Indoor environment is clean, in good repair, well-lighted, and well-ventilated. Fenced outdoor play space is available. Setting does not appear overcrowded when children are present.
Toys and equipment	Play materials are appropriate for infants and toddlers and are stored on low shelves within easy reach. Cribs, highchairs, infant seats, and child-sized tables and chairs are available. Outdoor equipment includes small riding toys, swings, slide, and sandbox.
Caregiver–child ratio	In child-care centers, caregiver–child ratio is no greater than 1 to 3 for infants and 1 to 6 for toddlers. Group size (number of children in one room) is no greater than 6 infants with 2 caregivers and 12 toddlers with 2 caregivers. In family child care, caregiver is responsible for no more than 6 children; within this group, no more than 2 are infants and toddlers. Staffing is consistent, so infants and toddlers can form relationships with particular caregivers.
Daily activities	Daily schedule includes times for active play, quiet play, naps, snacks, and meals. It is flexible rather than rigid, to meet the needs of individual children. Atmosphere is warm and supportive, and children are never left unsupervised.
Interactions among adults and children	Caregivers respond promptly to infants' and toddlers' distress; hold, talk to, sing to, and read to them; and interact with them in a manner that respects the individual child's interests and tolerance for stimulation.
Caregiver qualifications	Caregiver has some training in child development, first aid, and safety.
Relationships with parents	Parents are welcome anytime. Caregivers talk frequently with parents about children's behavior and development.
Licensing and accreditation	Child-care setting, whether a center or a home, is licensed by the state. Voluntary accreditation by the National Academy of Early Childhood Programs (www.naeyc.org/accreditation), or the National Association for Family Child Care (www.nafcc.org) is evidence of an especially high-quality program.

Source: Copple & Bredekamp, 2009.

See Applying What We Know above for signs of high-quality child toddlers, based on standards for **developmentally** devised by the U.S. National Associ

Milestones Tables

These beautifully illustrated tables summarize major developments within each topical area, providing a convenient overview of the chronology of development.

CHAPTER 4 Infancy: Early Learning, Motor Skills, and Perceptual Capacities 167

Milestones

Visual Development in Infancy

AGE	ACUITY, COLOR PERCEPTION, FOCUSING, AND EXPLORATION	DEPTH PERCEPTION	PATTERN PERCEPTION	OBJECT PERCEPTION
Birth–1 month	• Visual acuity is 20/600. • Scans the visual field and tracks moving objects.	• Responds to motion, blinking defensively when an object moves toward the face.	• Prefers large, bold patterns. • Responds to separate parts of a pattern, focusing on single, high-contrast features. • Prefers to look at simplified drawings of facelike patterns and at photos of faces with eyes open and a direct gaze. • Shows preference for attractive faces over less attractive ones.	• Displays size and shape constancy.
2–3 months	• Has adultlike focusing ability. • Scans more thoroughly and systematically.	• Responds to binocular depth cues.	• Prefers patterns with finer details. • Thoroughly scans internal pattern features. • Begins to perceive overall pattern structure. • Prefers complex drawings of human face to other, equally complex stimulus arrangements. • Prefers and more easily discriminates among female than male faces. • Recognizes and prefers mother's face and distinguishes among faces of strangers.	• Uses motion and spatial arrangement to identify objects.
4–5 months	• Color discrimination is adultlike.	• Sensitivity to binocular depth cues improves. • Begins to respond to pictorial depth cues.	• Perceives subjective boundaries in simple patterns. • Increasingly relies on relational information (such as distance among features) to differentiate faces. • Distinguishes emotionally positive from emotionally negative facial expressions.	• Uses shape, color, and texture to identify objects. • Perceives an object's path of movement as continuous without seeing the entire path.
6–9 months				
10–12 months				

In-Text Highlighted Key Terms with Definitions

Mastery of terms is promoted through in-text highlighting of key-term and concept definitions.

Boy or Girl?

Return to Figure 3.1, and note the 22 matching pairs of chromosomes, which geneticists number from longest (1) to shortest (22). These are called **autosomes** (meaning *not* sex chromosomes). The twenty-third pair consists of **sex chromosomes.** In females, this pair is called XX; in males, it is called XY. The X is a relatively large chromosome, whereas the Y is short and carries little genetic material. When gametes form in males, the X and Y chromosomes separate into different sperm cells. The gametes that form in females all carry an X chromosome. Therefore, the sex of the new organism is determined by whether an X-bearing or a Y-bearing sperm fertilizes the ovum. In fact, scientists have isolated a gene on the Y chromosome that initiates the formation of male sex organs during the prenatal period (Sekido & Lovell-Badge, 2009). But they also know that other genes, some yet to be discovered, are involved in the development of sexual characteristics.

Multiple Offspring

Sometimes a zygote that has started to duplicate separates into two clusters of cells that develop into two individuals. These are called **identical,** or **monozygotic,** twins because they have the same genetic makeup. The frequency of identical twins is the same around the world—about 1 in every 330 births (Hall, 2003). Animal research has uncovered a variety of environmental influences that prompt this type of twinning, including temperature changes, variation in oxygen levels, and late fertilization of the ovum. In a minority of cases, the identical twinning runs in families, suggesting a genetic influence (Lashley, 2007).

Fraternal, or **dizygotic, twins,** the most common type of multiple birth, result from the release and fertilization of two ova. Genetically, they are no more alike than ordinary siblings. Table 3.1 summarizes genetic and environmental factors that increase the chances of giving birth to fraternal twins. Older maternal age, fertility drugs, and in vitro fertilization (to be discussed shortly) are major causes of the dramatic rise in fraternal twinning and other multiple births in industrialized

End-of-Chapter Term List, and End-of-Book Glossary

Key terms also appear in an end-of-chapter page-referenced term list and an end-of-book page-referenced glossary.

8 *Unsurpassed Technology—MyDevelopmentLab*

Educators know it. Students know it. It's that inspired moment when something that was difficult to understand suddenly makes sense. Our MyLab products have been designed and refined with a single purpose in mind—to help educators create moments of understanding with their students.

MyDevelopmentLab ***delivers results*** in helping students succeed. Its automatically graded assessments, personalized study plan, and interactive eText provide ***engaging experiences*** that individualize, stimulate, and measure learning for each student.

MyDevelopmentLab includes:

- A **personalized study plan** for each student that promotes planning and strategic study of the subject matter, helping the student focus on areas in which he/she has weaker knowledge and understanding.
- **Assessment** tied to many chapter videos and applications, which enables both instructors and students to track progress and get immediate feedback.
- The **eText,** which lets students access their textbook anytime, anywhere.
- Extensive **video footage**, including **NEW** video segments and assessments.
- **Multimedia simulations**.
- **Biographies** of major figures in the field.
- **Mini-chapter on Emerging Adulthood**.
- **"Careers in Human Development,"** explains how knowledge of human development is essential for a wide range of career paths.

MyDevelopmentLab can be used by itself or linked to any learning management system. To learn more about how the new MyDevelopmentLab combines learning applications with powerful assessment, visit **www.mydevelopmentlab.com.**

9 *Valuable Teaching Resources*

MyDevelopmentLab for *Child Development*. Prepared in collaboration with Laura Berk, *MyDevelopmentLab* includes a variety of assessments that enable continuous evaluation of students' learning. Extensive video footage, multimedia simulations, "Careers in Human Development," and interactive activities—all unique to *Child Development*—are also included. See previous page.

Instructor's Resource Manual (IRM). Each chapter includes a Chapter-at-a-Glance grid, Brief Chapter Summary, Learning Objectives, detailed Lecture Outlines, Lecture Enhancements, Learning Activities, "Ask Yourself" questions with answers, Suggested Student Readings, and Media Materials list.

Test Bank. The Test Bank contains over 2,000 multiple-choice and essay questions, each page-referenced to chapter content and classified by type.

Computerized Test Bank. This computerized version of the Test Bank, in easy-to-use MyTest software, lets you prepare tests for printing as well as for network and online testing. It has full editing capability.

PowerPoint™ Presentation. The PowerPoint presentation provides illustrations and outlines of key topics for each chapter of the text. **A NEW video-enhanced version is also available to instructors.**

"Explorations in Child Development" DVD and Guide. This **NEW** DVD is over four hours in length and contains 47 four- to ten-minute narrated segments, designed for effective classroom use, that illustrate the many theories, concepts, and milestones of child development. **NEW** additions include *Preterm Birth, Autism, First-Grade Science Education, Childhood Obesity, Civic Engagement in Adolescence,* and *Changing Parent–Adolescent Relationships.*
